- b. Issue C.a of this manual first defines an assembler mnemonic for this encoding.
- c. UNDEFINED in ARMv4T.

### Change Processor State, and hints

The encoding of 32-bit T32 Change Processor State and hint instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	0					1	0														
												op1		op2																	

Table F3-14 shows the allocation of encodings in this space. Encodings with op1 set to 0b000 and a value of op2 that is not shown in the table are unallocated hints, and behave as if op2 is set to 0b00000000. These unallocated hint encodings are reserved and software must not use them.

**Table F3-14 Change Processor State, and hint instructions**

op1	op2	Instruction	See	Variant
not 000	-	Change Processor State	<a href="#">CPS (T32)</a> on page F7-3034	v6T2
000	00000000	No Operation hint	<a href="#">NOP</a> on page F7-2734	v6T2
	00000001	Yield hint	<a href="#">YIELD</a> on page F7-3026	v7
	00000010	Wait For Event hint	<a href="#">WFE</a> on page F7-3022	v7
	00000011	Wait For Interrupt hint	<a href="#">WFI</a> on page F7-3024	v7
	00000100	Send Event hint	<a href="#">SEV</a> on page F7-2804	v7
	00000101	Send Event Local hint	<a href="#">SEVL</a> on page F7-2805	v8
	1111xxxx	Debug hint	<a href="#">DBG</a> on page F7-2596	v7

## Miscellaneous control instructions

The encoding of some 32-bit T32 miscellaneous control instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	1					1	0		0					op							

Table F3-15 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED in ARMv7. They are UNPREDICTABLE in ARMv6T2.

**Table F3-15 Miscellaneous control instructions**

op	Instruction	See	Variant
0010	Clear-Exclusive	<a href="#">CLREX on page F7-2584</a>	v7
0100	Data Synchronization Barrier	<a href="#">DSB on page F7-2600</a>	v7
0101	Data Memory Barrier	<a href="#">DMB on page F7-2598</a>	v7
0110	Instruction Synchronization Barrier	<a href="#">ISB on page F7-2609</a>	v7

### F3.3.5 Load/store multiple

The encoding of 32-bit T32 load/store multiple instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	op	0	W	L			Rn																		

Table F3-16 shows the allocation of encodings in this space.

These encodings are all available in ARMv6T2 and above.

**Table F3-16 Load/store multiple instructions**

op	L	W:Rn	Instruction	See
00	0	-	Store Return State	<a href="#">SRS (T32) on page F7-3060</a>
	1	-	Return From Exception	<a href="#">RFE on page F7-3056</a>
01	0	-	Store Multiple (Increment After, Empty Ascending)	<a href="#">STM (STMIA, STMEA) on page F7-2870</a>

### F3.3.6 Load/store dual, load/store exclusive, table branch

The encoding of 32-bit T32 load/store dual, load/store exclusive and table branch instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	op1	1	op2	Rn						op3															

Table F3-17 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

**Table F3-17 Load/store double or exclusive, table branch**

1011	-	-	Subtract with Carry	<a href="#">SBC (register) on page F7-2794</a>
1101	-	not 11111	Subtract	<a href="#">SUB (register) on page F7-2918</a>
		11111	Compare	<a href="#">CMP (register) on page F7-2590</a>
1110	-	-	Reverse Subtract	<a href="#">RSB (register) on page F7-2784</a>

## Move register and immediate shifts

The encoding of the 32-bit T32 move register and immediate shift instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0														
1	1	1	0	1	0	1	0	0	1	0		1	1	1	1		imm3														imm2	type													

Table F3-23 shows the allocation of encodings in this space.

These encodings are all available in ARMv6T2 and above.

**Table F3-23 Move register and immediate shifts**

type	imm3:imm2	Instruction	See
00	00000	Move	<i>MOV (register, T32)</i> on page F7-2710
	not 00000	Logical Shift Left	<i>LSL (immediate)</i> on page F7-2692
01	-	Logical Shift Right	<i>LSR (immediate)</i> on page F7-2696
10	-	Arithmetic Shift Right	<i>ASR (immediate)</i> on page F7-2562
11	00000	Rotate Right with Extend	<i>RRX</i> on page F7-2780
	not 00000	Rotate Right	<i>ROR (immediate)</i> on page F7-2776

### F3.3.12 Data-processing (register)

The encoding of 32-bit T32 data-processing (register) instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	0	op1				Rn				1	1	1	1					op2							

If, in the second halfword of the instruction, bits[15:12] != 0b1111, the instruction is UNDEFINED.

Table F3-24 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

These encodings are all available in ARMv6T2 and above.

**Table F3-24 Data-processing (register)**

op1	op2	Rn	Instruction	See

0101	1xxx	not 1111	Unsigned Extend and Add Byte	<i>UXTAB</i> on page F7-3010
		1111	Unsigned Extend Byte	<i>UXTB</i> on page F7-3016
1xxx	00xx	-	-	<i>Parallel addition and subtraction, signed</i> on page F3-2459
	01xx	-	-	<i>Parallel addition and subtraction, unsigned</i> on page F3-2460
	10xx	-	-	<i>Miscellaneous operations</i> on page F3-2461

### F3.3.13 Parallel addition and subtraction, signed

The encoding of 32-bit T32 signed parallel addition and subtraction instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
1	1	1	1	1	0	1	0	1	op1										1	1	1	1					0	0	op2			

If, in the second halfword of the instruction, bits[15:12] != 0b1111, the instruction is UNDEFINED.

Table F3-25 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED. These encodings are all available in ARMv6T2 and above.

**Table F3-25 Signed parallel addition and subtraction instructions**

### F3.3.14 Parallel addition and subtraction, unsigned

The encoding of 32-bit T32 unsigned parallel addition and subtraction instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	0	1	op1						1	1	1	1	op2												

If, in the second halfword of the instruction, bits[15:12] != 0b1111, the instruction is UNDEFINED.

Table F3-26 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED. These encodings are all available in ARMv6T2 and above.

**Table F3-26 Unsigned parallel addition and subtraction instructions**

### F3.3.15 Miscellaneous operations

The encoding of some 32-bit T32 miscellaneous instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
1	1	1	1	1	0	1	0	1	op1										1	1	1	1					1	0	op2					

If, in the second halfword of the instruction, bits[15:12] != 0b1111, the instruction is UNDEFINED.

Table F3-27 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

# Chapter F4

## A32 Base Instruction Set Encoding

This chapter describes the encoding of the A32 instruction set. It contains the following sections:

- *A32 instruction set encoding* on page F4-2466.
- *Data-processing and miscellaneous instructions* on page F4-2468.
- *Load/store word and unsigned byte* on page F4-2480.
- *Media instructions* on page F4-2481.
- *Branch, branch with link, and block data transfer* on page F4-2486.
- *Coprocessor instructions, and Supervisor Call* on page F4-2487.
- *Unconditional instructions* on page F4-2488.

---

### Note

---

- Architecture variant information in this chapter describes the architecture variant or extension in which the instruction encoding was introduced into the A32 instruction set. *All* means that the instruction encoding was introduced in ARMv4 or earlier, and so is in all variants of the A32 instruction set covered by this manual.
  - In the decode tables in this chapter, an entry of - for a field value means the value of the field does not affect the decoding.
-

## F4.1 A32 instruction set encoding

The A32 instruction stream is a sequence of word-aligned words. Each A32 instruction is a single 32-bit word in that stream. The encoding of an A32 instruction is:

Table F4-1 shows the major subdivisions of the A32 instruction set, determined by bits[31:25, 4].

Most A32 instructions can be conditional, with a condition determined by bits[31:28] of the instruction, the cond field. For more information see *The condition code field*. This applies to all instructions except those with the cond field equal to 0b1111.

**Table F4-1 A32 instruction encoding**

cond	op1	op	Instruction classes
not 1111	00x	-	<i>Data-processing and miscellaneous instructions on page F4-2468.</i>
	010	-	<i>Load/store word and unsigned byte on page F4-2480.</i>
	011	0	<i>Load/store word and unsigned byte on page F4-2480.</i>
		1	<i>Media instructions on page F4-2481.</i>
	10x	-	<i>Branch, branch with link, and block data transfer on page F4-2486.</i>
	11x	-	<i>Coprocessor instructions, and Supervisor Call on page F4-2487.</i> Includes floating-point instructions and Advanced SIMD data transfers, see <a href="#">Chapter F5 T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings</a> .
1111	-	-	If the cond field is 0b1111, the instruction can only be executed unconditionally, see <i>Unconditional instructions on page F4-2488</i> . Includes Advanced SIMD instructions, see <a href="#">Chapter F5 T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings</a> .

### F4.1.1 The condition code field

Every conditional instruction contains a 4-bit condition code field, the cond field, in bits 31 to 28:

This field contains one of the values 0b0000-0b1110, as shown in [Table F2-1 on page F2-2416](#). Most instruction mnemonics can be extended with the letters defined in the *mnemonic extension* column of this table.

If the *always* (AL) condition is specified, the instruction is executed irrespective of the value of the condition flags. The absence of a condition code on an instruction mnemonic implies the AL condition code.

## F4.1.2 UNDEFINED and UNPREDICTABLE instruction set space

An attempt to execute an unallocated instruction results in either:

- Unpredictable behavior. The instruction is described as UNPREDICTABLE.  
ARMv8-A greatly reduces the architecturally UNPREDICTABLE behavior in AArch32 state. Many cases that earlier versions of the architecture describe as unpredictable become either:
  - CONSTRAINED UNPREDICTABLE, meaning the architecture defines a limited range of permitted behaviors.
  - Fully predictable.

For more information see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

The AArch32 parts of this manual might sometimes describe as UNPREDICTABLE behavior that ARMv8-A makes CONSTRAINED UNPREDICTABLE.

- An Undefined Instruction exception. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description, or in this chapter.

An instruction is UNPREDICTABLE if:

- It is declared as UNPREDICTABLE in an instruction description or in this chapter.
- The pseudocode for that encoding does not indicate that a different special case applies, and a bit marked (0) or (1) in the encoding diagram of an instruction is not 0 or 1 respectively.

For more information about UNDEFINED and UNPREDICTABLE instruction behavior, see [Undefined Instruction exception on page G1-3476](#).

Unless otherwise specified:

- A32 instructions introduced in an architecture variant are UNDEFINED in earlier architecture variants.
- A32 instructions introduced in one or more architecture extensions are UNDEFINED in an implementation that does not include any of those extensions.

## F4.1.3 The PC and the use of 0b1111 as a register specifier

In A32 instructions, the use of 0b1111 as a register specifier specifies the PC.

Many instructions are UNPREDICTABLE if they use 0b1111 as a register specifier. This is specified by pseudocode in the instruction description. ARMv8-A constrains the resulting UNPREDICTABLE behavior, see [Using R15 on page AppxA-4760](#).

———— **Note** —————

In ARMv7, ARM deprecates use of the PC as the base register in any store instruction.

## F4.1.4 The SP and the use of 0b1101 as a register specifier

In A32 instructions, the use of 0b1101 as a register specifier specifies the SP.

This applies to both A32 and T32 in AArch32 state. ARM deprecates using SP for any purpose other than as a stack pointer.

## F4.2 Data-processing and miscellaneous instructions

The encoding of A32 data-processing instructions, and some miscellaneous, instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	op		op1										op2														

Table F4-2 shows the allocation of encodings in this space.

**Table F4-2 Data-processing and miscellaneous instructions**

## F4.2.2 Data-processing (register-shifted register)

The encoding of A32 data-processing (register-shifted register) instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	0	op1																		0	op2		1				

Table F4-4 shows the allocation of encodings in this space. These encodings are in all architecture variants.

**Table F4-4 Data-processing (register-shifted register) instructions**

op1	op2	Instruction	See
0000x	-	Bitwise AND	<i>AND</i> (register-shifted register) on page F7-2560
0001x	-	Bitwise Exclusive OR	<i>EOR</i> (register-shifted register) on page F7-2606

0100x	-	Add	<i>ADD</i> (register-shifted register) on page F7-2547
0101x	-	Add with Carry	<i>ADC</i> (register-shifted register) on page F7-2538
0110x	-	Subtract with Carry	<i>SBC</i> (register-shifted register) on page F7-2796
0111x	-	Reverse Subtract with Carry	<i>RSC</i> (register-shifted register) on page F7-2789
10xx0	-	See <i>Data-processing and miscellaneous instructions</i> on page F4-2468	
10001	-	Test	<i>TST</i> (register-shifted register) on page F7-2952
10011	-	Test Equivalence	<i>TEQ</i> (register-shifted register) on page F7-2946
10101	-	Compare	<i>CMP</i> (register-shifted register) on page F7-2592
10111	-	Compare Negative	<i>CMN</i> (register-shifted register) on page F7-2588
1100x	-	Bitwise OR	<i>ORR</i> (register-shifted register) on page F7-2742
1101x	00	Logical Shift Left	<i>LSL</i> (register) on page F7-2694
	01	Logical Shift Right	<i>LSR</i> (register) on page F7-2698
	10	Arithmetic Shift Right	<i>ASR</i> (register) on page F7-2564
	11	Rotate Right	<i>ROR</i> (register) on page F7-2778
1110x	-	Bitwise Bit Clear	<i>BIC</i> (register-shifted register) on page F7-2574
1111x	-	Bitwise NOT	<i>MVN</i> (register-shifted register) on page F7-2732

### F4.2.3 Data-processing (immediate)

The encoding of A32 data-processing (immediate) instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	1	op				Rn																				

Table F4-5 shows the allocation of encodings in this space. These encodings are in all architecture variants.

**Table F4-5 Data-processing (immediate) instructions**

op	Rn	Instruction	See
0000x	-	Bitwise AND	<i>AND (immediate)</i> on page F7-2556
0001x	-	Bitwise Exclusive OR	<i>EOR (immediate)</i> on page F7-2602
0010x	not 1111	Subtract	<i>SUB (immediate, A32)</i> on page F7-2916
	1111	Form PC-relative address	<i>ADR</i> on page F7-2554
0011x	-	Reverse Subtract	<i>RSB (immediate)</i> on page F7-2782
0100x	not 1111	Add	<i>ADD (immediate, A32)</i> on page F7-2542
	1111	Form PC-relative address	<i>ADR</i> on page F7-2554
0101x	-	Add with Carry	<i>ADC (immediate)</i> on page F7-2534
0110x	-	Subtract with Carry	<i>SBC (immediate)</i> on page F7-2793
0111x	-	Reverse Subtract with Carry	<i>RSC (immediate)</i> on page F7-2787
10xx0	-	See <i>Data-processing and miscellaneous instructions</i> on page F4-2468	
10001	-	Test	<i>TST (immediate)</i> on page F7-2948
10011	-	Test Equivalence	<i>TEQ (immediate)</i> on page F7-2942
10101	-	Compare	<i>CMP (immediate)</i> on page F7-2589
10111	-	Compare Negative	<i>CMN (immediate)</i> on page F7-2586
1100x	-	Bitwise OR	<i>ORR (immediate)</i> on page F7-2738
1101x	-	Move	<i>MOV (immediate)</i> on page F7-2708
1110x	-	Bitwise Bit Clear	<i>BIC (immediate)</i> on page F7-2570
1111x	-	Bitwise NOT	<i>MVN (immediate)</i> on page F7-2728

These instructions all have modified immediate constants, rather than a simple 12-bit binary number. This provides a more useful range of values. For details see *Modified immediate constants in A32 instructions* on page F4-2472.

## F4.2.4 Modified immediate constants in A32 instructions

The encoding of a modified immediate constant in an A32 instruction is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
														rotation		a	b	c	d	e	f	g	h								

Table F4-6 shows the range of modified immediate constants available in A32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, and h bits and the rotation field in the instruction.

**Table F4-6 Encoding of modified immediates in A32 processing instructions**

rotation	<const> <sup>a</sup>
0000	00000000 00000000 00000000 abcdefgh
0001	gh000000 00000000 00000000 00abcdef
0010	efgh0000 00000000 00000000 0000abcd
0011	cdefgh00 00000000 00000000 000000ab
0100	abcdefgh 00000000 00000000 00000000
.	.
.	. 8-bit values shifted to other even-numbered positions
.	.
1001	00000000 00abcdef gh000000 00000000
.	.
.	. 8-bit values shifted to other even-numbered positions
.	.
1110	00000000 00000000 0000abcd efgh0000
1111	00000000 00000000 000000ab cdefgh00

a. This table shows the immediate constant value in binary form, to relate abcdefgh to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).

### Note

The range of values available in A32 modified immediate constants is slightly different from the range of values available in 32-bit T32 instructions. See *Modified immediate constants in T32 instructions* on page F3-2444.

### Carry out

A logical instruction with the rotation field set to 0b0000 does not affect APSR.C. Otherwise, a logical flag-setting instruction sets APSR.C to the value of bit[31] of the modified immediate constant.

### Constants with multiple encodings

Some constant values have multiple possible encodings. In this case, a UAL assembler must select the encoding with the lowest unsigned value of the rotation field. This is the encoding that appears first in Table F4-6. For example, the constant #3 must be encoded with (rotation, abcdefgh) == (0b0000, 0b00000011), not (0b0001, 0b00001100), (0b0010, 0b00110000), or (0b0011, 0b11000000).

In particular, this means that all constants in the range 0-255 are encoded with rotation == 0b0000, and permitted constants outside that range are encoded with rotation != 0b0000. A flag-setting logical instruction with a modified immediate constant therefore leaves APSR.C unchanged if the constant is in the range 0-255 and sets it to the most significant bit of the constant otherwise. This matches the behavior of T32 modified immediate constants for all constants that are permitted in both the A32 and T32 instruction sets.

An alternative syntax is available for a modified immediate constant that permits the programmer to specify the encoding directly. In this syntax, #<const> is instead written as #<byte>, #<rot>, where:

<byte> Is the numeric value of abcdefgh, in the range 0-255.

<rot> Is twice the numeric value of rotation, an even number in the range 0-30.

This syntax permits all A32 data-processing instructions with modified immediate constants to be disassembled to assembler syntax that assembles to the original instruction.

This syntax also makes it possible to write variants of some flag-setting logical instructions that have different effects on APSR.C to those obtained with the normal #<const> syntax. For example, ANDS R1, R2, #12, #2 has the same behavior as ANDS R1, R2, #3 except that it sets APSR.C to 0 instead of leaving it unchanged. Such variants of flag-setting logical instructions do not have equivalents in the T32 instruction set, and ARM deprecates their use.

### Operation of modified immediate constants, A32 instructions

```
// ARMEExpandImm()
// =====

bits(32) ARMEExpandImm(bits(12) imm12)

    // APSR.C argument to following function call does not affect the imm32 result.
    (imm32, -) = ARMEExpandImm_C(imm12, APSR.C);

    return imm32;

// ARMEExpandImm_C()
// =====

(bits(32), bit) ARMEExpandImm_C(bits(12) imm12, bit carry_in)

    unrotated_value = ZeroExtend(imm12<7:0>, 32);
    (imm32, carry_out) = Shift_C(unrotated_value, SRTYPE_ROR, 2*UInt(imm12<11:8>), carry_in);

    return (imm32, carry_out);
```

### F4.2.5 Multiply and multiply accumulate

The encoding of A32 multiply and multiply accumulate instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	0	op																1	0	0	1				

Table F4-7 shows the allocation of encodings in this space.

**Table F4-7 Multiply and multiply accumulate instructions**

op	Instruction	See	Variant
000x	Multiply	<a href="#">MUL on page F7-2726</a>	All
001x	Multiply Accumulate	<a href="#">MLA on page F7-2704</a>	All
0100	Unsigned Multiply Accumulate Accumulate Long	<a href="#">UMAAL on page F7-2978</a>	v6
0101	UNDEFINED	-	-
0110	Multiply and Subtract	<a href="#">MLS on page F7-2706</a>	v6T2
0111	UNDEFINED	-	-
100x	Unsigned Multiply Long	<a href="#">UMULL on page F7-2982</a>	All
101x	Unsigned Multiply Accumulate Long	<a href="#">UMLAL on page F7-2980</a>	All
110x	Signed Multiply Long	<a href="#">SMULL on page F7-2838</a>	All
111x	Signed Multiply Accumulate Long	<a href="#">SMLAL on page F7-2816</a>	All

### F4.2.6 Saturating addition and subtraction

The encoding of A32 saturating addition and subtraction instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	0	op				0													0	1	0	1		

Table F4-8 shows the allocation of encodings in this space. These encodings are all available in ARMv5TE and above, and are UNDEFINED in earlier variants of the architecture.

**Table F4-8 Saturating addition and subtraction instructions**

op	Instruction	See
00	Saturating Add	<a href="#">QADD on page F7-2762</a>
01	Saturating Subtract	<a href="#">QSUB on page F7-2769</a>
10	Saturating Double and Add	<a href="#">QDADD on page F7-2766</a>
11	Saturating Double and Subtract	<a href="#">QDSUB on page F7-2767</a>

## F4.2.7 Halfword multiply and multiply accumulate

The encoding of A32 halfword multiply and multiply accumulate instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
cond				0	0	0	1	0	op1				0													1	op		0			

Table F4-9 shows the allocation of encodings in this space.

These encodings are signed multiply (SMUL) and signed multiply accumulate (SMLA) instructions, operating on 16-bit values, or mixed 16-bit and 32-bit values. The results and accumulators are 32-bit or 64-bit.

These encodings are all available in ARMv5TE and above, and are UNDEFINED in earlier variants of the architecture.

**Table F4-9 Halfword multiply and multiply accumulate instructions**

op1	op	Instruction	See
00	-	Signed 16-bit multiply, 32-bit accumulate	<a href="#">SMLABB</a> , <a href="#">SMLABT</a> , <a href="#">SMLATB</a> , <a href="#">SMLATT</a> on page F7-2812

10	-	Signed 16-bit multiply, 64-bit accumulate	<a href="#">SMLALBB</a> , <a href="#">SMLALBT</a> , <a href="#">SMLALTB</a> , <a href="#">SMLALTT</a> on page F7-2818
11	-	Signed 16-bit multiply, 32-bit result	<a href="#">SMULBB</a> , <a href="#">SMULBT</a> , <a href="#">SMULTB</a> , <a href="#">SMULTT</a> on page F7-2836

## F4.2.8 Extra load/store instructions

The encoding of extra A32 load/store instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
cond				0	0	0	op1				Rn																1	op2		1			

If (op2 == 0b00) or (op1 == 0b0xx11) or (op1 == 0b0xx10 AND op2 == 0b0x) then see [Data-processing and miscellaneous instructions on page F4-2468](#).

Otherwise, Table F4-10 shows the allocation of encodings in this space.

**Table F4-10 Extra load/store instructions**

op2	op1	Rn	Instruction	See	Variant
01	xx0x0	-	Store Halfword	<a href="#">STRH (register)</a> on page F7-2908	All
	xx0x1	-	Load Halfword	<a href="#">LDRH (register)</a> on page F7-2670	All
	xx1x0	-	Store Halfword	<a href="#">STRH (immediate, A32)</a> on page F7-2906	All
	xx1x1	not 1111	Load Halfword	<a href="#">LDRH (immediate, A32)</a> on page F7-2666	All
		1111	Load Halfword	<a href="#">LDRH (literal)</a> on page F7-2668	All
10	xx0x0	-	Load Dual	<a href="#">LDRD (register)</a> on page F7-2658	v5TE
	xx0x1	-	Load Signed Byte	<a href="#">LDRSB (register)</a> on page F7-2678	All
	xx1x0	not 1111	Load Dual	<a href="#">LDRD (immediate)</a> on page F7-2654	v5TE
		1111	Load Dual	<a href="#">LDRD (literal)</a> on page F7-2656	v5TE
	xx1x1	not 1111	Load Signed Byte	<a href="#">LDRSB (immediate)</a> on page F7-2674	All
		1111	Load Signed Byte	<a href="#">LDRSB (literal)</a> on page F7-2676	All

**Table F4-10 Extra load/store instructions (continued)**

op2	op1	Rn	Instruction	See	Variant
11	xx0x0	-	Store Dual	<a href="#">STRD (register) on page F7-2894</a>	All
	xx0x1	-	Load Signed Halfword	<a href="#">LDRSH (register) on page F7-2686</a>	All
	xx1x0	-	Store Dual	<a href="#">STRD (immediate) on page F7-2892</a>	All
	xx1x1	not 1111	Load Signed Halfword	<a href="#">LDRSH (immediate) on page F7-2682</a>	All
		1111	Load Signed Halfword	<a href="#">LDRSH (literal) on page F7-2684</a>	All

#### F4.2.9 Extra load/store instructions, unprivileged

The encoding of unprivileged extra A32 load/store instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	0		1	op													1	op2	1						

If op2 == 0b00 then see [Data-processing and miscellaneous instructions on page F4-2468](#).

If (op == 0b0 AND op2 == 0b1x) then see [Extra load/store instructions on page F4-2475](#).

Otherwise, [Table F4-11](#) shows the allocation of encodings in this space.

**Table F4-11 Extra load/store instructions, unprivileged**

op2	op	Instruction	See	Variant
01	0	Store Halfword Unprivileged	<a href="#">STRHT on page F7-2910</a>	v6T2
	1	Load Halfword Unprivileged	<a href="#">LDRHT on page F7-2672</a>	v6T2
10	1	Load Signed Byte Unprivileged	<a href="#">LDRSBT on page F7-2680</a>	v6T2
11	1	Load Signed Halfword Unprivileged	<a href="#">LDRSHT on page F7-2688</a>	v6T2

## F4.2.10 Synchronization primitives

The encoding of A32 synchronization primitive instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	op								op1				1	0	0	1								

Table F4-12 shows the allocation of encodings in this space.

Other encodings in this space are UNDEFINED.

**Table F4-12**

op	op1	Instruction	See	Variant
1000	00	Store Release Word	<a href="#">STL on page F7-2856</a>	v8
	10	Store Release Exclusive Word	<a href="#">STLEX on page F7-2860</a>	v8
	11	Store Register Exclusive	<a href="#">STREX on page F7-2896</a>

1110	00	Store Release Halfword	<a href="#">STLH on page F7-2868</a>	v8
	10	Store Release Exclusive Halfword	<a href="#">STLEXH on page F7-2866</a>	v8
	11	Store Register Exclusive Halfword	<a href="#">STREXH on page F7-2902</a>	
1111	00	Load Acquire Halfword	<a href="#">LDAH on page F7-2618</a>	v8
	10	Load Acquire Exclusive Halfword	<a href="#">LDAEXH on page F7-2617</a>	v8
	11	Load Register Exclusive Halfword	<a href="#">LDREXH on page F7-2663</a>	

### F4.2.11 MSR (immediate), and hints

The encoding of A32 MSR (immediate) and hint instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	1	1	0	op		1	0	op1						op2												

Table F4-13 shows the allocation of encodings in this space. Encodings with op set to 0, op1 set to 0b000, and a value of op2 that is not shown in the table, are unallocated hints and behave as if op2 is set to 0b00000000. These unallocated hint encodings are reserved and software must not use them.

**Table F4-13 MSR (immediate), and hints**

op	op1	op2	Instruction	See	Variant
0	0000	00000000	No Operation hint	<a href="#">NOP on page F7-2734</a>	v6K, v6T2
		00000001	Yield hint	<a href="#">YIELD on page F7-3026</a>	v6K
		00000010	Wait For Event hint	<a href="#">WFE on page F7-3022</a>	v6K
		00000011	Wait For Interrupt hint	<a href="#">WFI on page F7-3024</a>	v6K
		00000100	Send Event hint	<a href="#">SEV on page F7-2804</a>	v6K
		00000101	Send Event Local hint	<a href="#">SEVL on page F7-2805</a>	v8

0100 1x00	-	-	Move to Special register, Application level	<a href="#">MSR (immediate) on page F7-2722</a>	All
		xx01 xx1x	Move to Special register, System level	<a href="#">MSR (immediate) on page F7-3052</a>	All
1	-	-	Move to Special register, System level	<a href="#">MSR (immediate) on page F7-3052</a>	All

## F4.2.12 Miscellaneous instructions

The encoding of some miscellaneous A32 instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	0	op	0	op1								B	0	op2										

Table F4-14 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

**Table F4-14 Miscellaneous instructions**

op2	B	op	op1	Instruction or instruction class	See	Variant

### F4.3 Load/store word and unsigned byte

The encoding of A32 load/store word and unsigned byte instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	1	A	op1				Rn								B												

These instructions have either A == 0 or B == 0. For instructions with A == 1 and B == 1, see [Media instructions on page F4-2481](#).

Otherwise, [Table F4-15](#) shows the allocation of encodings in this space. These encodings are in all architecture variants.

**Table F4-15 Single data transfer instructions**

1	0x111	0	-		

## F4.4 Media instructions

The encoding of A32 media instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	1	1	op1				Rd				op2				1	Rn											

Table F4-16 shows the allocation of encodings in this space.

Other encodings in this space are UNDEFINED.

**Table F4-16 Media instructions**

op1	op2	Rd	Rn	cond	Instructions	See	Variant
000xx	-	-	-	-	-	<i>Parallel addition and subtraction, signed on page F4-2482</i>

11111	111	-	-	1110	Permanently UNDEFINED	<i>UDF on page F7-2962</i>	All <sup>a</sup>
				not 1110		- <sup>a</sup>	All

a. Issue C.a of this manual first defines an assembler mnemonic for this encoding. This mnemonic applies only to the unconditional encoding, with cond set to 0b1110.

### F4.4.1 Parallel addition and subtraction, signed

The encoding of A32 signed parallel addition and subtraction instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	1	1	0	0	0	op1													op2	1							

Table F4-17 shows the allocation of encodings in this space. These encodings are all available in ARMv6 and above, and are UNDEFINED in earlier variants of the architecture.

Other encodings in this space are UNDEFINED.

**Table F4-17 Signed parallel addition and subtraction instructions**

op1	op2	Instruction	See
01	000	Add 16-bit	<a href="#">SADD16 on page F7-2791</a>

	010	Halving Subtract and Add with Exchange, 16-bit	<a href="#">SHSAX on page F7-2809</a>
	011	Halving Subtract 16-bit	<a href="#">SHSUB16 on page F7-2811</a>
	100	Halving Add 8-bit	<a href="#">SHADD8 on page F7-2806</a>
	111	Halving Subtract 8-bit	<a href="#">SHSUB8 on page F7-2810</a>

## F4.4.2 Parallel addition and subtraction, unsigned

The encoding of A32 unsigned parallel addition and subtraction instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	1	1	0	0	1	op1																op2		1			

Table F4-18 shows the allocation of encodings in this space. These encodings are all available in ARMv6 and above, and are UNDEFINED in earlier variants of the architecture.

Other encodings in this space are UNDEFINED.

**Table F4-18 Unsigned parallel addition and subtractions instructions**

op1	op2	Instruction	See

## F4.7.1 Memory hints, Advanced SIMD instructions, and miscellaneous instructions

The encoding of A32 memory hint and Advanced SIMD instructions, and some miscellaneous instruction is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	op1					Rn					op2																

Table F4-24 shows the allocation of encodings in this space.

Other encodings in this space are UNDEFINED in ARMv5 and above. All these encodings are UNPREDICTABLE in ARMv4 and ARMv4T.

# Chapter F5

## T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings

This chapter gives an overview of the Advanced SIMD and floating-point instruction sets. It contains the following sections:

- *Overview on page F5-2492.*
- *Advanced SIMD and floating-point instruction syntax on page F5-2493.*
- *Register encoding on page F5-2497.*
- *Advanced SIMD data-processing instructions on page F5-2499.*
- *Floating-point data-processing instructions on page F5-2511.*
- *Extension register load/store instructions on page F5-2514.*
- *Advanced SIMD element or structure load/store instructions on page F5-2515.*
- *8, 16, and 32-bit transfer between general-purpose and extension registers on page F5-2518.*
- *64-bit transfers between general-purpose and extension registers on page F5-2519.*

---

### Note

---

- The Advanced SIMD architecture, its associated implementations, and supporting software, are commonly referred to as NEON™ technology.
  - In the decode tables in this chapter, an entry of - for a field value means the value of the field does not affect the decoding.
-

## F5.1 Overview

All Advanced SIMD and floating-point instructions are available in both A32 and T32 instruction sets.

### F5.1.1 Advanced SIMD

The following sections describe the classes of Advanced SIMD instructions:

- [Advanced SIMD data-processing instructions](#) on page F5-2499.
- [Advanced SIMD element or structure load/store instructions](#) on page F5-2515.
- [Extension register load/store instructions](#) on page F5-2514.
- [8, 16, and 32-bit transfer between general-purpose and extension registers](#) on page F5-2518.
- [64-bit transfers between general-purpose and extension registers](#) on page F5-2519.

### F5.1.2 Floating-point

The following sections describe the classes of floating-point instructions:

- [Extension register load/store instructions](#) on page F5-2514.
- [8, 16, and 32-bit transfer between general-purpose and extension registers](#) on page F5-2518.
- [64-bit transfers between general-purpose and extension registers](#) on page F5-2519.
- [Floating-point data-processing instructions](#) on page F5-2511.

## F5.2 Advanced SIMD and floating-point instruction syntax

Advanced SIMD and floating-point instructions use the general conventions of the T32 and A32 instruction sets.

Advanced SIMD and floating-point data-processing instructions use the following general format:

```
V{<modifier>}<operation>{<shape>}{<c>}{<q>}{.<dt>} {<dest>}, <src1>, <src2>
```

All Advanced SIMD and floating-point instructions begin with a V. This distinguishes Advanced SIMD vector and floating-point instructions from scalar instructions.

The main operation is specified in the <operation> field. It is usually a three letter mnemonic the same as or similar to the corresponding scalar integer instruction.

The <c> and <q> fields are standard assembler syntax fields. For details see [Standard assembler syntax fields on page F2-2415](#).

### F5.2.1 Advanced SIMD instruction modifiers

The <modifier> field provides additional variants of some instructions. [Table F5-1](#) provides definitions of the modifiers. Modifiers are not available for every instruction.

**Table F5-1 Advanced SIMD instruction modifiers**

<modifier>	Meaning
Q	The operation uses saturating arithmetic.
R	The operation performs rounding.
D	The operation doubles the result (before accumulation, if any).
H	The operation halves the result.

### F5.2.2 Advanced SIMD operand shapes

The <shape> field provides additional variants of some instructions. [Table F5-2](#) provides definitions of the shapes. Operand shapes are not available for every instruction.

**Table F5-2 Advanced SIMD operand shapes**

<shape>	Meaning	Typical register shape
(none)	The operands and result are all the same width.	Dd, Dn, Dm    Qd, Qn, Qm
L	Long operation - result is twice the width of both operands	Qd, Dn, Dm
N	Narrow operation - result is half the width of both operands	Dd, Qn, Qm
W	Wide operation - result and first operand are twice the width of the second operand	Qd, Qn, Dm

**Note**

- Some assemblers support a Q shape specifier, that requires all operands to be Q registers. An example of using this specifier is `VADDQ.S32 q0, q1, q2`. This is not standard UAL, and ARM recommends that programmers do not use a Q shape specifier.
- A disassembler must not generate any shape specifier not shown in [Table F5-2](#).

### F5.2.3 Data type specifiers

The <dt> field normally contains one data type specifier. Unless the assembler syntax description for the instruction indicates otherwise, this indicates the data type contained in:

- The second operand, if any.
- The operand, if there is no second operand.
- The result, if there are no operand registers.

The data types of the other operand and result are implied by the <dt> field combined with the instruction shape. For information about data type formats see [Data types supported by the Advanced SIMD implementation on page E1-2305](#).

In the instruction syntax descriptions in [Chapter F2 About the T32 and A32 Instruction Descriptions](#), the <dt> field is usually specified as a single field. However, where more convenient, it is sometimes specified as a concatenation of two fields, <type><size>.

#### Syntax flexibility

There is some flexibility in the data type specifier syntax:

- Software can specify three data types, specifying the result and both operand data types. For example:  
 VSUBW.I16.I16.S8 Q3, Q5, D0 instead of VSUBW.S8 Q3, Q5, D0
- Software can specify two data types, specifying the data types of the two operands. The data type of the result is implied by the instruction shape. For example:  
 VSUBW.I16.S8 Q3, Q5, D0 instead of VSUBW.S8 Q3, Q5, D0
- Software can specify two data types, specifying the data types of the single operand and the result. For example:  
 VMOVN.I16.I32 D0, Q1 instead of VMOVN.I32 D0, Q1
- Where an instruction requires a less specific data type, software can instead specify a more specific type, as shown in [Table F5-3](#).
- Where an instruction does not require a data type, software can provide one.
- The F32 data type can be abbreviated to F.
- The F64 data type can be abbreviated to D.

In all cases, if software provides additional information, the additional information must match the instruction shape. Disassembly does not regenerate this additional information.

**Table F5-3 Data type specification flexibility**

Specified data type	Permitted more specific data types				
None	Any				
.I<size>	-	.S<size>	.U<size>	-	-
.8	.I8	.S8	.U8	.P8	-
.16	.I16	.S16	.U16	.P16	.F16
.32	.I32	.S32	.U32	-	.F32 or .F
.64	.I64	.S64	.U64	-	.F64 or .D

## F5.2.4 Register specifiers

The <dest>, <src1>, and <src2> fields contain register specifiers, or in some cases scalar specifiers or register lists. [Table F5-4](#) shows the register and scalar specifier formats that appear in the instruction descriptions.

If <dest> is omitted, it is the same as <src1>.

**Table F5-4 Advanced SIMD and floating-point register specifier formats**

<b>&lt;specifier&gt;</b>	<b>Usual meaning <sup>a</sup></b>	<b>Used in</b>
<Qd>	A quadword destination register for the result vector.	Advanced SIMD
<Qn>	A quadword source register for the first operand vector.	Advanced SIMD
<Qm>	A quadword source register for the second operand vector.	Advanced SIMD
<Dd>	A doubleword destination register for the result vector.	Both
<Dn>	A doubleword source register for the first operand vector.	Both
<Dm>	A doubleword source register for the second operand vector.	Both
<Sd>	A singleword destination register for the result vector.	Floating-point
<Sn>	A singleword source register for the first operand vector.	Floating-point
<Sm>	A singleword source register for the second operand vector.	Floating-point
<Dd[x]>	A destination scalar for the result. Element x of vector <Dd>.	Advanced SIMD
<Dn[x]>	A source scalar for the first operand. Element x of vector <Dn>.	Both <sup>b</sup>
<Dm[x]>	A source scalar for the second operand. Element x of vector <Dm>.	Advanced SIMD
<Rt>	A general-purpose register, used for a source or destination address.	Both
<Rt2>	A general-purpose register, used for a source or destination address.	Both
<Rn>	A general-purpose register, used as a load or store base address.	Both
<Rm>	A general-purpose register, used as a post-indexed address source.	Both

a. In some instructions the roles of registers are different.

b. In the floating-point instructions, <Dn[x]> is used only in *VMOV* (scalar to general-purpose register), see [VMOV \(scalar to general-purpose register\)](#) on page F8-3220.

## F5.2.5 Register lists

A register list is a list of register specifiers separated by commas and enclosed in brackets { and }. There are restrictions on what registers can appear in a register list. These restrictions are described in the individual instruction descriptions. Table F5-5 shows some register list formats, with examples of actual register lists corresponding to those formats.

———— **Note** —————

Register lists must not wrap around the end of the register bank.

---

### Syntax flexibility

There is some flexibility in the register list syntax:

- Where a register list contains consecutive registers, they can be specified as a range, instead of listing every register, for example {D0-D3} instead of {D0, D1, D2, D3}.
- Where a register list contains an even number of consecutive doubleword registers starting with an even numbered register, it can be written as a list of quadword registers instead, for example {Q1, Q2} instead of {D2-D5}.
- Where a register list contains only one register, the enclosing braces can be omitted, for example VLD1.8 D0, [R0] instead of VLD1.8 {D0}, [R0].

**Table F5-5 Example register lists**

Format	Example	Alternative
{<Dd>}	{D3}	D3
{<Dd>, <Dd+1>, <Dd+2>}	{D3, D4, D5}	{D3-D5}
{<Dd[x]>, <Dd+2[x]>}	{D0[3], D2[3]}	-
{<Dd[ ]>}	{D7[ ]}	D7[ ]

## F5.3 Register encoding

An Advanced SIMD register is either:

- *quadword*, meaning it is 128 bits wide.
- *doubleword*, meaning it is 64 bits wide.

Some instructions have options for either doubleword or quadword registers. This is normally encoded in Q, bit[6], as Q = 0 for doubleword operations, or Q = 1 for quadword operations.

A floating-point register is either:

- Double-precision, meaning it is 64 bits wide.
- Single-precision, meaning it is 32 bits wide.

This is encoded in the sz field, bit[8], as sz = 1 for double-precision operations, or sz = 0 for single-precision operations.

The T32 instruction encoding of Advanced SIMD or floating-point registers is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
										D	Vn					Vd					sz	N	Q	M	Vm						

The A32 instruction encoding of Advanced SIMD or floating-point registers is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
										D	Vn					Vd					sz	N	Q	M	Vm						

Some instructions use only one or two registers, and use the unused register fields as additional opcode bits.

Table F5-6 shows the encodings for the registers.

**Table F5-6 Encoding of register numbers**

Register mnemonic	Usual usage	Register number encoded in <sup>a</sup>	Notes <sup>a</sup>	Used in
<Qd>	Destination (quadword)	D, Vd (bits[22, 15:13])	bit[12] == 0 <sup>b</sup>	Advanced SIMD
<Qn>	First operand (quadword)	N, Vn (bits[7, 19:17])	bit[16] == 0 <sup>b</sup>	Advanced SIMD
<Qm>	Second operand (quadword)	M, Vm (bits[5, 3:1])	bit[0] == 0 <sup>b</sup>	Advanced SIMD
<Dd>	Destination (doubleword)	D, Vd (bits[22, 15:12])	-	Both
<Dn>	First operand (doubleword)	N, Vn (bits[7, 19:16])	-	Both
<Dm>	Second operand (doubleword)	M, Vm (bits[5, 3:0])	-	Both
<Sd>	Destination (single-precision)	Vd, D (bits[15:12, 22])	-	Floating-point
<Sn>	First operand (single-precision)	Vn, N (bits[19:16, 7])	-	Floating-point
<Sm>	Second operand (single-precision)	Vm, M (bits[3:0, 5])	-	Floating-point

a. Bit numbers given for the A32 instruction encoding. See the figures in this section for the equivalent bits in the T32 encoding.

b. If this bit is 1, the instruction is UNDEFINED.

### F5.3.1 Advanced SIMD scalars

Advanced SIMD scalars can be 8-bit, 16-bit, 32-bit, or 64-bit. Instructions other than multiply instructions can access any element in the register set. The instruction syntax refers to the scalars using an index into a doubleword vector. The descriptions of the individual instructions contain details of the encodings.

Table F5-7 shows the form of encoding for scalars used in multiply instructions. These instructions cannot access scalars in some registers. The descriptions of the individual instructions contain cross references to this section where appropriate.

32-bit Advanced SIMD scalars, when used as single-precision floating-point numbers, are equivalent to Floating-point single-precision registers. That is,  $D_m[x]$  in a 32-bit context ( $0 \leq m \leq 15, 0 \leq x \leq 1$ ) is equivalent to  $S[2m + x]$ .

**Table F5-7 Encoding of scalars in multiply instructions**

Scalar mnemonic	Usual usage	Scalar size	Register specifier	Index specifier	Accessible registers
<D <sub>m</sub> [x]>	Second operand	16-bit	V <sub>m</sub> [2:0]	M, V <sub>m</sub> [3]	D0-D7
		32-bit	V <sub>m</sub> [3:0]	M	D0-D15

## F5.4 Advanced SIMD data-processing instructions

The T32 encoding of Advanced SIMD data processing instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	U	1	1	1	1	A								B				C											

The A32 encoding of Advanced SIMD data processing instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	U	A								B				C											

Table F5-8 shows the encoding for Advanced SIMD data-processing instructions. Other encodings in this space are UNDEFINED.

In these instructions, the U bit is in a different location in A32 and T32 instructions. This is bit[12] of the first halfword in the T32 encoding, and bit[24] in the A32 encoding. Other variable bits are in identical locations in the two encodings, after adjusting for the fact that the A32 encoding is held in memory as a single word and the T32 encoding is held as two consecutive halfwords.

The A32 instructions can only be executed unconditionally. The T32 instructions can be executed conditionally by using the IT instruction. For details see *IT* on page F7-2610.

**Table F5-8 Data-processing instructions**

U	A	B	C	See

### F5.4.1 Three registers of the same length

The T32 encoding of these instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	U	1	1	1	1	0		C												A			B						

The A32 encoding of these instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	U	0			C												A			B					

Table F5-9 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

## F5.4.2 Three registers of different lengths

The T32 encoding of these instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	U	1	1	1	1	1			B											A		0	0						

The A32 encoding of these instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	U	1			B												A		0	0					

If B == 0b11, see [Advanced SIMD data-processing instructions on page F5-2499](#).

Otherwise, [Table F5-10](#) shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

## F5.4.4 Two registers and a shift amount

The T32 encoding of these instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	U	1	1	1	1	1		imm3						A	L	B													

The A32 encoding of these instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	U	1		imm3																					

If [L, imm3] == 0b0000, see [One register and a modified immediate value on page F5-2508](#).

Otherwise, [Table F5-12](#) shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

	1110	Vector Move	<i>VMOV (immediate)</i> on page F8-3214
	1111	UNDEFINED	-

Table F5-15 shows the modified immediate constants available with these instructions, and how they are encoded.

**Table F5-15 Modified immediate values for Advanced SIMD instructions**

op	cmode	Constant <sup>a</sup>	<dt> <sup>b</sup>	Notes
-	000x	00000000 00000000 00000000 abcdefgh 00000000 00000000 00000000 abcdefgh	I32	c
	001x	00000000 00000000 abcdefgh 00000000 00000000 00000000 abcdefgh 00000000	I32	c, d
	010x	00000000 abcdefgh 00000000 00000000 00000000 abcdefgh 00000000 00000000	I32	c, d
	011x	abcdefgh 00000000 00000000 00000000 abcdefgh 00000000 00000000 00000000	I32	c, d
	100x	00000000 abcdefgh 00000000 abcdefgh 00000000 abcdefgh 00000000 abcdefgh	I16	c
	101x	abcdefgh 00000000 abcdefgh 00000000 abcdefgh 00000000 abcdefgh 00000000	I16	c, d
	1100	00000000 00000000 abcdefgh 11111111 00000000 00000000 abcdefgh 11111111	I32	d, e
	1101	00000000 abcdefgh 11111111 11111111 00000000 abcdefgh 11111111 11111111	I32	d, e

**Table F5-15 Modified immediate values for Advanced SIMD instructions (continued)**

op	cmode	Constant <sup>a</sup>	<dt> <sup>b</sup>	Notes
0	1110	abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh	I8	f
	1111	aBbbbbbc defgh000 00000000 00000000 aBbbbbbc defgh000 00000000 00000000	F32	f, g
1	1110	aaaaaaaa bbbbbbbb cccccccc dddddddd eeeeeeee ffffffff gggggggg hhhhhhhh	I64	f
	1111	UNDEFINED	-	-

- a. In this table, the immediate value is shown in binary form, to relate abcdefgh to the encoding diagram. In assembler syntax, the constant is specified by a data type and a value of that type. That value is specified in the normal way (a decimal number by default) and is replicated enough times to fill the 64-bit immediate. For example, a data type of I32 and a value of 10 specify the 64-bit constant 0x0000000A0000000A.
- b. This specifies the data type used when the instruction is disassembled. On assembly, the data type must be matched in the table if possible. Other data types are permitted as pseudo-instructions when a program is assembled, provided the 64-bit constant specified by the data type and value is available for the instruction. If a constant is available in more than one way, the first entry in this table that can produce it is used. For example, VMOV.I64 D0, #0x8000000080000000 does not specify a 64-bit constant that is available from the I64 line of the table, but does specify one that is available from the fourth I32 line or the F32 line. It is assembled to the first of these, and therefore is disassembled as VMOV.I32 D0, #0x80000000.
- c. This constant is available for the VBIC, VMOV, VMVN, and VORR instructions.
- d. UNPREDICTABLE if abcdefgh == 00000000.
- e. This constant is available for the VMOV and VMVN instructions only.
- f. This constant is available for the VMOV instruction only.
- g. In this entry, B = NOT(b). The bit pattern represents the floating-point number  $(-1)^S \times 2^{\text{exp}} \times \text{mantissa}$ , where  $S = \text{UInt}(a)$ ,  $\text{exp} = \text{UInt}(\text{NOT}(b):c:d)-3$  and  $\text{mantissa} = (16+\text{UInt}(e:f:g:h))/16$ .

        imm8e = Replicate(imm8<3>, 8); imm8f = Replicate(imm8<2>, 8);
        imm8g = Replicate(imm8<1>, 8); imm8h = Replicate(imm8<0>, 8);
        imm64 = imm8a:imm8b:imm8c:imm8d:imm8e:imm8f:imm8g:imm8h;
      if cmode<0> == '1' && op == '0' then
        imm32 = imm8<7>:NOT(imm8<6>):Replicate(imm8<6>,5):imm8<5:0>:Zeros(19);
        imm64 = Replicate(imm32, 2);
      if cmode<0> == '1' && op == '1' then
        if UsingAArch32() then ReservedEncoding();
        imm64 = imm8<7>:NOT(imm8<6>):Replicate(imm8<6>,8):imm8<5:0>:Zeros(48);

  return imm64;
```

## F5.5 Floating-point data-processing instructions

The T32 encoding of floating-point data processing instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	T	1	1	1	0	opc1	opc2					1	0	1	opc3	0	opc4												

The A32 encoding of floating-point data processing instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
cond	1	1	1	0	opc1	opc2						1	0	1	opc3	0	opc4																

- [Table F5-16](#) shows the encodings for three-register floating-point data-processing instructions. Other encodings in this space are UNDEFINED.
- [Table F5-17](#) applies only if [Table F5-16](#) indicates that it does. It shows the encodings for floating-point data-processing instructions with two registers or a register and an immediate. Other encodings in this space are UNDEFINED.
- [Table F5-18 on page F5-2512](#) shows the immediate constants available in the VMOV (immediate) instruction.

These instructions are CDP instructions for coprocessors 10 and 11.

a. VFPv3 Half-precision Extension.

**Table F5-18 Floating-point modified immediate constants**

Data type	opc2	opc4	Constant <sup>a</sup>
F32	abcd	efgh	aBbbbbbc defgh000 00000000 00000000
F64	abcd	efgh	aBbbbbbb bbcdefgh 00000000 00000000 00000000 00000000 00000000 00000000

a. In this column, B = NOT(b). The bit pattern represents the floating-point number  $(-1)^S \times 2^{\text{exp}} \times \text{mantissa}$ , where  $S = \text{UInt}(a)$ ,  $\text{exp} = \text{UInt}(\text{NOT}(b):c:d) - 3$  and  $\text{mantissa} = (16 + \text{UInt}(e:f:g:h)) / 16$ .

## F5.5.1 Operation of modified immediate constants, floating-point

The VFPEExpandImm() pseudocode function describes the operation of an immediate constant in a floating-point instruction.

```
// VFPEExpandImm()
// =====

bits(N) VFPEExpandImm(bits(8) imm8)
    assert N IN {32,64};
    constant integer E = (if N == 32 then 8 else 11);
    constant integer F = N - E - 1;
    sign = imm8<7>;
    exp = NOT(imm8<6>):Replicate(imm8<6>,E-3):imm8<5:4>;
    frac = imm8<3:0>:Zeros(F-4);
    return sign : exp : frac;
```

## F5.6 Extension register load/store instructions

The T32 encoding of Advanced SIMD and floating-point register load and store instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	T	1	1	0	Opcode				Rn				1 0 1																

The A32 encoding of Advanced SIMD and floating-point register load and store instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			1	1	0	Opcode				Rn				1 0 1																	

If T == 1 in the T32 encoding or cond == 0b1111 in the A32 encoding, the instruction is UNDEFINED.

Otherwise, the allocation of encodings in this space is shown in [Table F5-19](#). Other encodings in this space are UNDEFINED.

These instructions are LDC and STC instructions for coprocessors 10 and 11.

**Table F5-19 Extension register load/store instructions**

Opcode	Rn	Instruction	See

10x11	-	Vector Load Multiple (Decrement Before, writeback)	<i>VLDM on page F8-3198</i>

## F5.7 Advanced SIMD element or structure load/store instructions

The T32 encoding of Advanced SIMD element load and store instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	0	1	A			L	0												B							

The A32 encoding of Advanced SIMD element load and store instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	0	0	A			L	0												B							

The allocation of encodings in this space is shown in:

- [Table F5-20](#) if L == 0. These are the encodings for store instructions.
- [Table F5-21 on page F5-2516](#) if L == 1. These are the encodings for load instructions.

Other encodings in this space are UNDEFINED.

The variable bits are in identical locations in the two encodings, after adjusting for the fact that the A32 encoding is held in memory as a single word and the T32 encoding is held as two consecutive halfwords.

The A32 instructions can only be executed unconditionally. The T32 instructions can be executed conditionally by using the IT instruction. For details see [IT on page F7-2610](#).

**Table F5-20 Element and structure store instructions (L == 0)**

	0x10 1010	Vector Load	<i>VLD3 (single 3-element structure to one lane)</i> on page F8-3188
	1110	Vector Load	<i>VLD3 (single 3-element structure to all lanes)</i> on page F8-3190
	0x11 1011	Vector Load	<i>VLD4 (single 4-element structure to one lane)</i> on page F8-3194
	1111	Vector Load	<i>VLD4 (single 4-element structure to all lanes)</i> on page F8-3196

## F5.7.1 Advanced SIMD addressing mode

All the element and structure load/store instructions use this addressing mode. There is a choice of three formats:

- [<Rn>{:<align>}]      The address is contained in general-purpose register Rn.  
Rn is not updated by this instruction.  
Encoded as Rm = 0b1111.  
If Rn is encoded as 0b1111, the instruction is UNPREDICTABLE.
- [<Rn>{:<align>}]!      The address is contained in general-purpose register Rn.  
Rn is updated by this instruction:  $Rn = Rn + transfer\_size$   
Encoded as Rm = 0b1101.  
  
transfer\_size is the number of bytes transferred by the instruction. This means that, after the instruction is executed, Rn points to the address in memory immediately following the last address loaded from or stored to.  
If Rn is encoded as 0b1111, the instruction is UNPREDICTABLE.  
This addressing mode can also be written as:  
[<Rn>{:<align>}], #<transfer\_size>  
However, disassembly produces the [<Rn>{:<align>}]! form.
- [<Rn>{:<align>}], <Rm>  
The address is contained in general-purpose register <Rn>.  
Rn is updated by this instruction:  $Rn = Rn + Rm$   
Encoded as Rm = Rm. Rm must not be encoded as 0b1111 or 0b1101, the PC or the SP.  
If Rn is encoded as 0b1111, the instruction is UNPREDICTABLE.

In all cases, <align> specifies an alignment. Details are given in the individual instruction descriptions.

Previous versions of the document used the @ character for alignment. So, for example, the first format in this section was shown as [<Rn>{@<align>}]. Both @ and : are supported. However, to ensure portability of code to assemblers that treat @ as a comment character, : is preferred.

## F5.8 8, 16, and 32-bit transfer between general-purpose and extension registers

The T32 encoding of Advanced SIMD and floating-point 8-bit, 16-bit, and 32-bit register data transfer instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	T	1	1	1	0	A	L							1	0	1	C			B	1								

The A32 encoding of Advanced SIMD and floating-point 8-bit, 16-bit, and 32-bit register data transfer instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
cond				1	1	1	0	A	L															1	0	1	C			B	1		

If T == 1 in the T32 encoding or cond == 0b1111 in the A32 encoding, the instruction is UNDEFINED.

Otherwise, the allocation of encodings in this space is shown in [Table F5-22](#). Other encodings in this space are UNDEFINED.

These instructions are MRC and MCR instructions for coprocessors 10 and 11.

**Table F5-22 8-bit, 16-bit and 32-bit data transfer instructions**

L	C	A	B	Instruction	See
0	0	000	-	Vector Move	<i>VMOV</i> (between general-purpose register and single-precision register) on page F8-3222
		111	-	Move to floating-point Special register from general-purpose register	<i>VMSR</i> on page F8-3234 <i>VMSR</i> on page F7-3072, System level view

1	xxx	-	-	Vector Move	<i>VMOV</i> (scalar to general-purpose register) on page F8-3220

## F5.9 64-bit transfers between general-purpose and extension registers

The T32 encoding of Advanced SIMD and floating-point 64-bit register data transfer instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	T	1	1	0	0	0	1	0						1	0	1	C	op											

The A32 encoding of Advanced SIMD and floating-point 64-bit register data transfer instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
cond				1	1	0	0	0	1	0											1	0	1	C	op							

If T == 1 in the T32 encoding or cond == 0b1111 in the A32 encoding, the instruction is UNDEFINED.

Otherwise, the allocation of encodings in this space is shown in [Table F5-23](#). Other encodings in this space are UNDEFINED.

These instructions are MRRC and MCRR instructions for coprocessors 10 and 11.

**Table F5-23 64-bit data transfer instructions**

C	op	Instruction
0	00x1	<i>VMOV (between two general-purpose registers and two single-precision registers) on page F8-3224</i>
1	00x1	<i>VMOV (between two general-purpose registers and a doubleword extension register) on page F8-3226</i>

# Chapter F6

## ARMv8 Changes to the T32 and A32 Instruction Sets

This chapter summarizes the changes that ARMv8 makes to the T32 and A32 instruction sets. It contains the following section:

- *The A32 and T32 instruction sets on page F6-2522.*
- *Partial Deprecation of IT on page F6-2523.*
- *New A32 and T32 Load-Acquire/Store-Release instructions on page F6-2524.*
- *New A32 and T32 scalar floating-point instructions on page F6-2525.*
- *New A32 and T32 Advanced SIMD floating-point instructions on page F6-2528.*
- *New A32 and T32 cryptography instructions on page F6-2530.*
- *New A32 and T32 System instructions on page F6-2531.*

## F6.1 The A32 and T32 instruction sets

This chapter describes the changes that ARMv8-A makes to the T32 and A32 instruction sets, compared to an ARMv7-A implementation that includes all of the following extensions:

- Multiprocessing Extensions.
- Large Physical Address Extension.
- Virtualization Extensions.
- Security Extensions.
- VFPv4.
- Advanced SIMDv2.

The implemented instructions are not affected by whether the ARMv8-A implementation includes either or both of EL2 and EL3.

ARMv8-A obsoletes the A32 SWP and SWPB instructions.

ARM deprecates any use of the following instructions. In ARMv8-A, privileged software can disable these instructions:

- A32 and T32 CP15 barriers [CP15DSB](#), [CP15ISB](#), and [CP15DMB](#).
- A32 and T32 SETEND instruction.
- A subset of T32 IT instruction functionality, as described in [Partial Deprecation of IT on page F6-2523](#).

ARMv8-A adds new A32 and T32 instructions to align with some of the features introduced in the A64 instruction set. These are described in:

- [Partial Deprecation of IT on page F6-2523](#).
- [New A32 and T32 Load-Acquire/Store-Release instructions on page F6-2524](#).
- [New A32 and T32 scalar floating-point instructions on page F6-2525](#).
- [New A32 and T32 Advanced SIMD floating-point instructions on page F6-2528](#).
- [New A32 and T32 cryptography instructions on page F6-2530](#).
- [New A32 and T32 System instructions on page F6-2531](#).

---

### Note

The existing A32 and T32 assembler syntax is unchanged from ARMv7 UAL. Where the syntax term <c> is used in this chapter, it represents a standard ARM condition code. Mnemonics that do not include <c> can not be conditionally executed.

---

## F6.2 Partial Deprecation of IT

ARMv8-A deprecates some uses of the T32 IT instruction. All uses of IT that apply to instructions other than a single subsequent 16-bit instruction from a restricted set are deprecated, as are explicit references to the PC within that single 16-bit instruction. This permits the non-deprecated forms of IT and subsequent instructions to be treated as a single 32-bit conditional instruction. The restricted set of 16-bit instructions which are not deprecated when used in conjunction with IT are listed in [Table F6-1](#).

**Table F6-1 Non-deprecated IT 16-bit conditional instructions**

Permitted 16-bit instructions	Class	Notes
MOV, MVN	Move	Deprecated when Rm or Rd is the PC.
LDR, LDRB, LDRH, LDRSB, LDRSH	Load	Deprecated for PC-relative load literal forms
STR, STRB, STRH	Store	-
ADD, ADC, RSB, SBC, SUB	Add/Subtract	Deprecated for ADD SP, SP, #imm, SUB SP, SP, #imm, and when Rm, Rdn, or Rdm is the PC
CMP, CMN	Compare	Deprecated when Rm or Rn is the PC
MUL	Multiply	-
ASR, LSL, LSR, ROR	Shift	-
AND, BIC, EOR, ORR, TST	Logical	-
BX, BLX	Branch to register	Deprecated when Rm is the PC

———— **Note** —————

The ARMv7 IT instruction functionality remains available in order to execute ARMv7 T32 code. However, to verify conformance with the deprecation, a new control bit permits privileged software to disable the deprecated forms of the IT instruction, so that their use generates an Undefined Instruction exception. See [HSCTLR.ITD](#).

## F6.3 New A32 and T32 Load-Acquire/Store-Release instructions

The new Load-Acquire/Store-Release instructions must be naturally aligned. LDRAEXD and STRLEXD must be aligned to 8 bytes. An unaligned address causes an alignment fault. For more information about the ordering of Load-Acquire/Store-Release, see [Load-Acquire, Store-Release on page E2-2355](#).

### F6.3.1 A32 and T32 Load-Acquire/Store-Release (non-exclusive) instructions

[Table F6-2](#) lists the new A32 and T32 Load-Acquire/Store-Release (non-exclusive) instructions.

**Table F6-2 A32 and T32 Load-Acquire/Store-Release (non-exclusive) instructions**

Mnemonic	Instruction	See
LDA	Load-Acquire Word	<a href="#">LDA on page F7-2612</a>
LDAB	Load-Acquire Byte	<a href="#">LDAB on page F7-2613</a>

STLEXH	Store-Release Exclusive Halfword	<a href="#">STLEXH on page F7-2866</a>

## F6.4 New A32 and T32 scalar floating-point instructions

This section describes the new A32 and T32 scalar floating-point instructions. It contains the following subsections:

- [A32 and T32 floating-point conditional select.](#)
- [A32 and T32 floating-point minimum and maximum numeric.](#)
- [A32 and T32 floating-point to integer conversion.](#)
- [A32 and T32 floating-point conversion between half-precision and double-precision on page F6-2526.](#)
- [A32 and T32 floating-point round to integral on page F6-2526.](#)

### F6.4.1 A32 and T32 floating-point conditional select

The new VSEL instruction conditionally copies one of its two source registers to the destination register. For A32 it provides an alternative to a pair of conditional VMOV instructions, while for T32 it compensates for the partial deprecation of IT instruction described in [Partial Deprecation of IT on page F6-2523](#), since it does not require an IT prefix.

[Table F6-4](#) lists the A32 and T32 floating-point conditional select instructions

**Table F6-4 A32 and T32 Conditional select**

Mnemonic	Instruction	See
VSEL	Conditional select	<a href="#">VSEL on page F8-3336</a>

### F6.4.2 A32 and T32 floating-point minimum and maximum numeric

The new VMAXNM and VMINNM instructions implement the  $\text{minNum}(x,y)$  and  $\text{maxNum}(x,y)$  operations defined by the IEEE754-2008 standard. They return the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to VFP VMAX and VMIN. These instructions cannot be conditionally executed.

[Table F6-5](#) lists the A32 and T32 floating-point minNum and maxNum instructions.

**Table F6-5 A32 and T32 floating-point minNum and maxNum instructions**

Mnemonic	Instruction	See
VMAXNM	Single-precision maxNum (scalar)	<a href="#">on page F8-3204 VMAXNM,</a> <a href="#">VMINNM on page F8-3206</a>
VMINNM	Double-precision minNum (scalar)	

### F6.4.3 A32 and T32 floating-point to integer conversion

These new instructions extend the ARMv7 VFP VCVT instructions by providing four additional explicit rounding modes. The syntax term  $\langle r \rangle$  selects the rounding direction as follows:

- N** Round to nearest, with ties to even.
- A** Round to nearest, with ties to away.
- P** Round towards positive infinity.
- M** Round towards minus infinity.

These instructions cannot be conditionally executed.

Table F6-6 lists the A32 and T32 FP to integer conversion instructions.

**Table F6-6 A32 and T32 floating-point to integer conversion instructions**

Mnemonic	Instruction	See
VCVT	Floating-point convert to integer	<i>VCVTIA, VCVTN, VCVTP, VCVTM (between floating-point and integer, floating-point) on page F8-3154</i>

#### F6.4.4 A32 and T32 floating-point conversion between half-precision and double-precision

The VFP VCVTT and VCVTB instructions are extended to permit direct conversion between half-precision and double-precision floating-point as a single operation, preventing double rounding errors. The syntax term <y> in Table F6-7 is either T, top half, and B, bottom half.

Table F6-7 lists the A32 and T32 instructions to convert between half-precision and double-precision floating-point values.

**Table F6-7 A32 and T32 floating-point precision conversion**

Mnemonic	Instruction	See
VCVTB	Floating-point convert single-precision to double-precision	<i>VCVTB, VCVTT on page F8-3156</i>
VCVTT	Floating-point convert double-precision to single-precision	

#### F6.4.5 A32 and T32 floating-point round to integral

The new round to integral instructions round a floating-point value to the nearest integral floating-point value of the same size. The floating-point exceptions that can be raised by these instructions are the Invalid operation, for a signaling NaN input, or Input Denormal, for a denormal input when flush-to-zero mode is enabled. For VRINTX only an Inexact exception can be raised if the result is numeric and does not have the same numerical value as the source. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal floating-point arithmetic.

A subset of the rounding instructions can be conditionally executed when the syntax term <x> selects the rounding direction as follows:

- Z** Round towards zero.
- R** FPSCR rounding mode.
- X** FPSCR rounding mode and signaling inexactness.

Table F6-9 on page F6-2527 lists the A32 and T32 round to integral instructions that can be conditionally executed.

**Table F6-8 A32 and T32 floating-point round to integral instruction (unconditional)**

Mnemonic	Instruction	See
VRINT	Floating-point round to integral	<ul style="list-style-type: none"> <li>• <i>VRINTX (floating-point) on page F8-3316</i></li> <li>• <i>VRINTZ, VRINTR (floating-point) on page F8-3320</i></li> </ul>

The remaining rounding instructions cannot be conditionally executed when the syntax term <r> selects the rounding directions as follows:

- N** Round to nearest, with ties to even.
- A** Round to nearest, with ties to away.
- P** Round towards positive infinity.

**M** Round towards minus infinity.

**Table F6-9 A32 and T32 floating-point round to integral instruction (conditional)**

<b>Mnemonic</b>	<b>Instruction</b>	<b>See</b>
<a href="#">VRINT</a> on <a href="#">page F8-3310</a>	Floating-point round to integral	<a href="#">VRINTA</a> , <a href="#">VRINTN</a> , <a href="#">VRINTP</a> , <a href="#">VRINTM</a> ( <i>floating-point</i> ) on <a href="#">page F8-3312</a>

[Table F6-8 on page F6-2526](#) lists the A32 and T32 round to integral instructions that cannot be conditionally executed.

## F6.5 New A32 and T32 Advanced SIMD floating-point instructions

The AArch32 Advanced SIMD extension continues to support only single-precision, 32-bit, floating-point data types, with fixed operating modes of Round to Nearest, Default NaN, and Flush-to-Zero. However, it is extended with the addition of the instructions in the following subsections:

- [A32 and T32 floating-point minimum and maximum numeric](#).
- [A32 and T32 floating-point conversion](#).
- [A32 and T32 floating-point round to integral](#).

### F6.5.1 A32 and T32 floating-point minimum and maximum numeric

Vector forms of the new VMAXNM and VMINNM instructions are described in [A32 and T32 floating-point minimum and maximum numeric](#) on page F6-2525.

Table F6-10 lists the A32 and T32 floating-point minNum/maxNum instructions.

**Table F6-10 A32 and T32 floating-point minNum/maxNum instructions**

Mnemonic	Instruction	See
VMAXNM	Single-precision maxNum (vector)	<a href="#">VMAXNM</a> , <a href="#">VMINNM</a> on page F8-3206
VMINNM	Double-precision minNum (vector)	

### F6.5.2 A32 and T32 floating-point conversion

Vector forms of the floating-point to integer conversion instructions are described in [A32 and T32 floating-point to integer conversion](#) on page F6-2525. The syntax term <r> selects the rounding direction as follows:

- N** Round to nearest, with ties to even.
- A** Round to nearest, with ties to away.
- P** Round towards positive infinity.
- M** Round towards minus infinity.

Table F6-11 lists the A32 and T32 floating-point conversion instructions.

**Table F6-11 A32 and T32 floating-point conversion instructions**

Mnemonic	Instruction	See
VCVT	Floating-point convert to integer	<a href="#">VCVTA</a> , <a href="#">VCVTN</a> , <a href="#">VCVTP</a> , <a href="#">VCVTM</a> ( <a href="#">between floating-point and integer, Advanced SIMD</a> ) on page F8-3152

### F6.5.3 A32 and T32 floating-point round to integral

Vector forms of the floating-point rounding instructions are described in [A32 and T32 floating-point round to integral](#) on page F6-2526. The syntax term <rx> selects the rounding direction as follows:

- N** Round to the nearest, with ties to even.
- A** Round to the nearest, with ties to away.
- P** Round towards positive infinity.
- M** Round towards minus infinity.
- Z** Round towards zero.
- X** Round to the nearest, with ties to even, signaling inexactness.

Table F6-12 on page F6-2529 lists the A32 and T32 floating-point round to integral instructions.

**Table F6-12 A32 and T32 SIMD floating-point round to integral instructions**

<b>Mnemonic</b>	<b>Instruction</b>	<b>See</b>
VRINT	Floating-point round to integral	<ul style="list-style-type: none"><li>• <a href="#">VRINTX (Advanced SIMD)</a> on page F8-3314</li><li>• <a href="#">VRINTZ (Advanced SIMD)</a> on page F8-3318</li><li>• <a href="#">VRINTA, VRINTN, VRINTP, VRINTM (Advanced SIMD)</a> on page F8-3310</li></ul>

## F6.6 New A32 and T32 cryptography instructions

The optional Cryptography extension instructions share the SIMD and floating-point register file. For more information see:

- *Announcing the Advanced Encryption Standard.*
- *The Galois/Counter Mode of Operation.*
- *Announcing the Secure Hash Standard.*

Table F6-13 lists the A32 and T32 cryptography instructions.

**Table F6-13 A32 and T32 Cryptography instructions**

Mnemonic	Instruction	See
AESD	AES single round decryption	<a href="#">AESD on page F8-3076</a>
AESE	AED single round encryption	<a href="#">AESE on page F8-3077</a>
AESIMC	AES inverse mix columns	<a href="#">AESIMC on page F8-3078</a>
AESMC	AES mix columns	<a href="#">AESMC on page F8-3079</a>
SHA1C	SHA1 hash update accelerator, choose	<a href="#">SHA1C on page F8-3081</a>
SHA1M	SHA1 hash update accelerator, majority	<a href="#">SHA1M on page F8-3083</a>
SHA1P	SHA1 hash update accelerator, parity	<a href="#">SHA1P on page F8-3084</a>
SHA1H	SHA1 hash update accelerator, rotate left by 30	<a href="#">SHA1H on page F8-3082</a>
SHA1SU0	SHA1 schedule update accelerator, first part	<a href="#">SHA1SU0 on page F8-3085</a>
SHA1SU1	SHA1 schedule update accelerator, second part	<a href="#">SHA1SU1 on page F8-3086</a>
SHA256H	SHA256 hash update accelerator	<a href="#">SHA256H on page F8-3087</a>
SHA256H2	SHA256 hash update accelerator upper part	<a href="#">SHA256H2 on page F8-3088</a>
SHA256SU0	SHA256 schedule update accelerator, first part	<a href="#">SHA256SU0 on page F8-3089</a>
SHA256SU1	SHA256 schedule update accelerator, second part	<a href="#">SHA256SU1 on page F8-3090</a>
VMULL	Polynomial multiply long, 64×64 to 128-bit	<a href="#">VMUL, VMULL (integer and polynomial) on page F8-3236</a>

## F6.7 New A32 and T32 System instructions

The section describes the system instructions. It contains the following subsections:

- [External Debug](#).
- [Barriers and hints](#).
- [TLB Maintenance](#).

### F6.7.1 External Debug

[Table F6-14](#) lists the new External Debug support instructions.

**Table F6-14 External Debug support instructions**

Mnemonic	Instructions	Note
DCPS1	Debug switch to EL1, valid in External Debug state only	-
DCPS2	Debug switch to EL2, valid in External Debug state only	-
DCPS3	Debug switch to EL3, valid in External Debug state only	-
HLT #uimm6	Halting mode software breakpoint	Enters External Debug state if enabled, else treated as UNALLOCATED, with a 6-bit payload in uimm6

### F6.7.2 Barriers and hints

There are new A32 and T32 barrier options and hint instructions.

[Table F6-15](#) lists the new A32 and T32 barrier instructions.

**Table F6-15 Additional barrier instructions**

Mnemonic	Notes
DMB {ISHLD, OSHLD, NSHLD, LD}	Data Memory Barrier is extended to support the new Load-Load/Store options
DSB {ISHLD, OSHLD, NSHLD, LD}	Data Synchronization Barrier is extended to support the new Load-Load/Store options
SEVL	Send Event Locally without the requirement to affect other processors, for example to prime a wait-loop which starts with a WFE instructions

### F6.7.3 TLB Maintenance

TLB maintenance operations that are only required to apply to the last level translation table walk of the first stage of translation are added to A32 and T32 as shown in [Table F6-16](#). See [Translation Lookaside Buffers \(TLBs\) on page G3-3630](#) and [TLB maintenance requirements on page G3-3633](#)

**Table F6-16 Additional A32 and T32 TLB maintenance instructions**

Mnemonic	Relation to existing A32/T32 operation
TLBIMVALIS	Related to the TLBIMVAIS operation
TLBIMVAALIS	Related to the TLBIMVAAIS operation
TLBIMVALHIS	Related to the TLBIMVAHIS operation
TLBIMVAL	Related to the TLBIMVA operation

**Table F6-16 Additional A32 and T32 TLB maintenance instructions (continued)**

Mnemonic	Relation to existing A32/T32 operation
TLBIMVAAL	Related to the TLBIMVAA operation
TLBIMVALH	Related to the TLBIMVAH operation

A32 and T32 instructions contain TLB maintenance operations that must apply to individual entries from stage2 TLB structures, which hold IPA to PA translations. These are consistent with the A64 TLBI system instructions described in *New A32 and T32 System instructions on page F6-2531*. The relation between the A32 and T32 instructions and the A64 instructions is shown in [Table F6-17](#)

**Table F6-17 Relation of A32 TLB maintenance instructions to A64 instructions**

Instruction	Relation to A64 operation
TLBIIPAS2IS	Equivalent to IPAS2E1IS
TLBIIPAS2LIS	Equivalent to IPAS2LE1IS Related to existing A32/T32 TLBIIPAS2IS operation
TLBIIPAS2	Equivalent to the A64 IPAS2E1 operation
TLBIIPAS2L	Equivalent to IPAS2LE1 operation Related to existing A32/T32 TLBIIPAS2 operation

**Note**

These new system operations are accessed using the MCR instruction or, if implemented, by an assembler using the SYS mnemonic followed by the TLBI operation name.

# Chapter F7

## T32 and A32 Base Instruction Set Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- *Alphabetical list of T32 and A32 base instruction set instructions on page F7-2534.*
- *General restrictions on system instructions on page F7-3028.*
- *Encoding and use of Banked register transfer instructions on page F7-3029.*
- *Alphabetical list of system instructions on page F7-3033.*

## F7.1 Alphabetical list of T32 and A32 base instruction set instructions

This section lists every instruction in the T32 and A32 base instruction sets. For details of the format used see [Format of instruction descriptions on page F2-2410](#).

This section is formatted so that a full description of an instruction uses a double page.

### F7.1.1 ADC (immediate)

Add with Carry (immediate) adds an immediate value and the Carry flag value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding T1** ARMv6T2, ARMv7

ADC{S}<c> <Rd>, <Rn>, #<const>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	i	0	1	0	1	0	S		Rn		0	imm3		Rd													imm8

d = UInt(Rd); n = UInt(Rn); setflags = (S == '1'); imm32 = ThumbExpandImm(i:imm3:imm8);  
 if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

ADC{S}<c> <Rd>, <Rn>, #<const>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	1	0	1	0	1	S		Rn		Rd	imm12																	

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;  
 d = UInt(Rd); n = UInt(Rn); setflags = (S == '1'); imm32 = ARMEExpandImm(imm12);

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

ADC{S}{<c>}{<q>} {<Rd>}, <Rn>, #<const>

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>     See *Standard assembler syntax fields* on page F2-2415.
- <Rd>        The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions (T32)* on page F7-3066 or *SUBS PC, LR and related instructions (A32)* on page F7-3068.
- In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2296.
- <Rn>        The first operand register. The PC can be used in A32 instructions.
- <const>     The immediate value to be added to the value obtained from <Rn>. See *Modified immediate constants in T32 instructions* on page F3-2444 or *Modified immediate constants in A32 instructions* on page F4-2472 for the range of values.

The pre-UAL syntax ADC<c>S is equivalent to ADCS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcvc) = AddWithCarry(R[n], imm32, APSR.C);
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.<N,Z,C,V> = nzcvc;
```

## F7.1.2 ADC (register)

Add with Carry (register) adds a register value, the Carry flag value, and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding T1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7  
 ADCS <Rdn>, <Rm> Outside IT block.  
 ADC<c> <Rdn>, <Rm> Inside IT block.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	0	0	1	0	1	Rm	Rdn				

d = UInt(Rdn); n = UInt(Rdn); m = UInt(Rm); setflags = !InITBlock();  
 (shift\_t, shift\_n) = (SRTYPE\_LSL, 0);

**Encoding T2** ARMv6T2, ARMv7  
 ADC{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	1	1	0	1	0	S	Rn				(0)	imm3	Rd	imm2	type	Rm										

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');  
 (shift\_t, shift\_n) = DecodeImmShift(type, imm3:imm2);  
 if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7  
 ADC{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	0	0	1	0	1	S	Rn				Rd	imm5				type	0	Rm									

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;  
 d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');  
 (shift\_t, shift\_n) = DecodeImmShift(type, imm5);

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

ADC{S}{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift>}

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>     See *Standard assembler syntax fields* on page F2-2415.
- <Rd>        The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions (T32)* on page F7-3066 or *SUBS PC, LR and related instructions (A32)* on page F7-3068.
- In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2296.
- <Rn>        The first operand register. The PC can be used in A32 instructions.
- <Rm>        The optionally shifted second operand register. The PC can be used in A32 instructions.
- <shift>     The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and any encoding is permitted. *Shifts applied to a register* on page F2-2419 describes the shifts and how they are encoded.

In T32 assembly:

- Outside an IT block, if ADCS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADCS <Rd>, <Rn> had been written.
- Inside an IT block, if ADC<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADC<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax ADC<c>S is equivalent to ADCS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, APSR.C);
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.<N,Z,C,V> = nzcv;
```

### F7.1.3 ADC (register-shifted register)

Add with Carry (register-shifted register) adds a register value, the Carry flag value, and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

ADC{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	0	0	1	0	1	S	Rn				Rd				Rs		0	type		1	Rm						

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

ADC{S}{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, <type> <Rs>

where:

S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<Rn> The first operand register.

<Rm> The register that is shifted and used as the second operand.

<type> The type of shift to apply to the value read from <Rm>. It must be one of:

ASR Arithmetic shift right, encoded as type = 0b10.

LSL Logical shift left, encoded as type = 0b00.

LSR Logical shift right, encoded as type = 0b01.

ROR Rotate right, encoded as type = 0b11.

<Rs> The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax ADC<c>S is equivalent to ADCS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, APSR.C);
    R[d] = result;
    if setflags then
        APSR.<N,Z,C,V> = nzcv;
```

### F7.1.4 ADD (immediate, T32)

This instruction adds an immediate value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding T1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7  
 ADDS <Rd>, <Rn>, #<imm3> Outside IT block.  
 ADD<c> <Rd>, <Rn>, #<imm3> Inside IT block.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	1	1	0	imm3			Rn			Rd		

d = UInt(Rd); n = UInt(Rn); setflags = !InITBlock(); imm32 = ZeroExtend(imm3, 32);

**Encoding T2** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

## Assembler syntax

ADD{S}{<c>}{<q>} {<Rd>}, <Rn>, #<const> All encodings permitted  
ADDW{<c>}{<q>} {<Rd>}, <Rn>, #<const> Only encoding T4 permitted

where:

S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<Rn> The first operand register. If <Rn> is SP, see [ADD \(SP plus immediate\) on page F7-2548](#). If <Rn> is PC, see [ADR on page F7-2554](#).

<const> The immediate value to be added to the value obtained from <Rn>. The range of values is 0-7 for encoding T1, 0-255 for encoding T2 and 0-4095 for encoding T4. See [Modified immediate constants in T32 instructions on page F3-2444](#) for the range of values for encoding T3.

When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4 (if encoding T4 is required, use the ADDW syntax). Encoding T1 is preferred to encoding T2 if <Rd> is specified and encoding T2 is preferred to encoding T1 if <Rd> is omitted.

The pre-UAL syntax ADD<c>S is equivalent to ADDS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcV) = AddWithCarry(R[n], imm32, '0');
    R[d] = result;
    if setflags then
        APSR.<N,Z,C,V> = nzcV;
```

### F7.1.5 ADD (immediate, A32)

This instruction adds an immediate value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

ADD{S}<c> <Rd>, <Rn>, #<const>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	1	0	1	0	0	S	Rn				Rd				imm12

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if (d == 15 && S == '0') || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

ADD{S}{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift>}

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>      See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>        The destination register. If S is specified and <Rd> is the PC, see [CMN \(register\) on page F7-2587](#). If omitted, <Rd> is the same as <Rn> and encoding T2 is preferred to encoding T1 inside an IT block. If <Rd> is present, encoding T1 is preferred to encoding T2.
- If <Rd> is the PC and S is not specified, encoding T2 is used and the instruction is a branch to the address calculated by the operation. This is a simple branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
- <Rn>        The first operand register. The PC can be used in encoding T2. If <Rn> is SP, see [ADD \(SP plus register, T32\) on page F7-2550](#).
- <Rm>        The register that is optionally shifted and used as the second operand. The PC can be used in encoding T2.
- <shift>      The shift to apply to the value read from <Rm>. If present, only encoding T3 is permitted. If omitted, no shift is applied and any encoding is permitted. [Shifts applied to a register on page F2-2419](#) describes the shifts and how they are encoded.

Inside an IT block, if ADD<c> <Rd>, <Rn>, <Rd> cannot be assembled using encoding T1, it is assembled using encoding T2 as though ADD<c> <Rd>, <Rn> had been written. To prevent this happening, use the .W qualifier.

The pre-UAL syntax ADD<c>S is equivalent to ADDS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, nzcvc) = AddWithCarry(R[n], shifted, '0');
    if d == 15 then
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.<N,Z,C,V> = nzcvc;
```

## F7.1.7 ADD (register, A32)

This instruction adds a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

ADD{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}

## Assembler syntax

ADD{S}{<c>}{<q>} {<Rd>}, SP, #<const>                    All encodings permitted  
ADDW{<c>}{<q>} {<Rd>}, SP, #<const>                    Only encoding T4 is permitted

where:

S                    If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q>            See *Standard assembler syntax fields* on page F2-2415.

<Rd>                The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions (T32)* on page F7-3066 or *SUBS PC, LR and related instructions (A32)* on page F7-3068. If omitted, <Rd> is SP.

                    In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2296.

<const>            The immediate value to be added to the value obtained from SP. Values are multiples of 4 in the range 0-1020 for encoding T1, multiples of 4 in the range 0-508 for encoding T2 and any value in the range 0-4095 for encoding T4. See *Modified immediate constants in T32 instructions* on page F3-2444 or *Modified immediate constants in A32 instructions* on page F4-2472 for the range of values for encodings T3 and A1.

                    When both 32-bit encodings are available for an instruction, encoding T3 is preferred to encoding T4.

### **Note**

If encoding T4 is required, use the ADDW syntax.

The pre-UAL syntax ADD<c>S is equivalent to ADDS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(SP, imm32, '0');
    if d == 15 then                    // Can only occur for ARM encoding

        if setflags then
            APSR.<N,Z,C,V> = nzcvc;
```

### F7.1.11 ADD (SP plus register, A32)

This instruction adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

ADD{S}<c> <Rd>, SP, <Rm>{, <shift>}

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	0	1	0	0	S	1	1	0	1	Rd				imm5				type	0	Rm					

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;  
 d = UInt(Rd); m = UInt(Rm); setflags = (S == '1');  
 (shift\_t, shift\_n) = DecodeImmShift(type, imm5);

## Assembler syntax

ADD{S}{<c>}{<q>} {<Rd>}, SP, <Rm>{, <shift>}

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>     See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>        The destination register. If S is specified and <Rd> is the PC, see [SUBS PC, LR and related instructions \(A32\) on page F7-3068](#). This register can be SP. If omitted, <Rd> is SP. This register can be the PC, but ARM deprecates using the PC.
- If S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
- <Rm>        The register that is optionally shifted and used as the second operand. This register can be the PC, but ARM deprecates using the PC. This register can be the SP, but ARM deprecates using the SP.
- <shift>     The shift to apply to the value read from <Rm>. If omitted, no shift is applied and any encoding is permitted. [Shifts applied to a register on page F2-2419](#) describes the shifts and how they are encoded.

The pre-UAL syntax ADD<c>S is equivalent to ADDS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, nzcv) = AddWithCarry(SP, shifted, '0');
    if d == 15 then
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.<N,Z,C,V> = nzcv;
```

## F7.1.12 ADR

This instruction adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.

### Encoding T1 ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

ADR<c> <Rd>, <label>

## Assembler syntax

ADR{<c>}{<q>} <Rd>, <label>	Normal syntax
ADD{<c>}{<q>} <Rd>, PC, #<const>	Alternative for encodings T1, T3, A1
SUB{<c>}{<q>} <Rd>, PC, #<const>	Alternative for encoding T2, A2

where:

<c>, <q>	See <a href="#">Standard assembler syntax fields on page F2-2415</a> .
<Rd>	The destination register. In A32 instructions, if <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see <a href="#">Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296</a> .
<label>	The label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the <code>Align(PC, 4)</code> value of the ADR instruction to this label.  If the offset is zero or positive, encodings T1, T3, and A1 are permitted, with <code>imm32</code> equal to the offset.  If the offset is negative, encodings T2 and A2 are permitted, with <code>imm32</code> equal to the size of the offset. That is, the use of encoding T2 or A2 indicates that the required offset is minus the value of <code>imm32</code> .  Permitted values of the size of the offset are:  <b>Encoding T1</b> Multiples of 4 in the range 0 to 1020. <b>Encodings T2, T3</b> Any value in the range 0 to 4095. <b>Encodings A1, A2</b> Any of the constants described in <a href="#">Modified immediate constants in A32 instructions on page F4-2472</a> .

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2380](#).

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    if d == 15 then // Can only occur for ARM encodings
        ALUWritePC(result);
    else
        R[d] = result;
```

### F7.1.13 AND (immediate)

This instruction performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

#### Encoding T1 ARMv6T2, ARMv7

AND{S}<c> <Rd>, <Rn>, #<const>

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1');
(imm32, carry) = ARMEExpandImm_C(imm12, APSR.C);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

AND{S}{<c>}{<q>} {<Rd>}, <Rn>, #<const>

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>     See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>        The destination register. If S is specified and <Rd> is the PC, see [SUBS PC, LR and related instructions \(T32\) on page F7-3066](#) or [SUBS PC, LR and related instructions \(A32\) on page F7-3068](#).  
In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
- <Rn>        The first operand register. The PC can be used in A32 instructions.
- <const>     The immediate value to be ANDed with the value obtained from <Rn>. See [Modified immediate constants in T32 instructions on page F3-2444](#) or [Modified immediate constants in A32 instructions on page F4-2472](#) for the range of values.

The pre-UAL syntax AND<c>S is equivalent to ANDS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND imm32;
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

### F7.1.14 AND (register)

This instruction performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

#### Encoding T1 ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

ANDS <Rdn>, <Rm> Outside IT block.

```
if Rd == '1111' && S == '1' then SEE TST (register);
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if (d == 15 && S == '0') || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

#### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

AND{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	0	0	0	0	0	0	S	Rn				Rd				imm5					type	0	Rm					

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

AND{S}{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift>}

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>      See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>        The destination register. If S is specified and <Rd> is the PC, see [SUBS PC, LR and related instructions \(T32\) on page F7-3066](#) or [SUBS PC, LR and related instructions \(A32\) on page F7-3068](#).  
In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
- <Rn>        The first operand register. The PC can be used in A32 instructions.
- <Rm>        The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.
- <shift>      The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. [Shifts applied to a register on page F2-2419](#) describes the shifts and how they are encoded.

In T32 assembly:

- Outside an IT block, if ANDS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ANDS <Rd>, <Rn> had been written.
- Inside an IT block, if AND<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though AND<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax AND<c>S is equivalent to ANDS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] AND shifted;
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

### F7.1.15 AND (register-shifted register)

This instruction performs a bitwise AND of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

AND{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	0	0	0	0	0	S	Rn				Rd				Rs		0	type		1	Rm						

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

AND{S}{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, <type> <Rs>

where:

S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<Rn> The first operand register.

<Rm> The register that is shifted and used as the second operand.

<type> The type of shift to apply to the value read from <Rm>. It must be one of:

ASR Arithmetic shift right, encoded as type = 0b10.

LSL Logical shift left, encoded as type = 0b00.

LSR Logical shift right, encoded as type = 0b01.

ROR Rotate right, encoded as type = 0b11.

<Rs> The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax AND<c>S is equivalent to ANDS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] AND shifted;
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
    // APSR.V unchanged
```

## F7.1.16 ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register. It can optionally update the condition flags based on the result.

ASR{S}{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

where:

S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q>     See [Standard assembler syntax fields on page F2-2415](#).

<Rd>        The destination register.

<Rn>        The first operand register.

<Rm>        The register whose bottom byte contains the amount to shift by.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[m]<7:0>);
    (result, carry) = Shift_C(R[n], SRTYPE_ASR, shift_n, APSR.C);
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        // APSR.V unchanged
```

## F7.1.18 B

Branch causes a branch to a target address.

### Encoding T1 ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

B<c> <label> Not permitted in IT block.

 if InITBlock() && !LastInITBlock() then UNPREDICTABLE;

### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

B<c> <label>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1	0	1	0	imm24																							

imm32 = SignExtend(imm24:'00', 32);

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

**Related encodings** See [Branches and miscellaneous control](#) on page F3-2447.

## Assembler syntax

B{<c>}{<q>} <label>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

### Note

Encodings T1 and T3 are conditional in their own right, and do not require an IT instruction to make them conditional.

For encodings T1 and T3, <c> must not be AL or omitted. The 4-bit encoding of the condition is placed in the instruction and not in a preceding IT instruction, and the instruction must not be in an IT block. As a result, encodings T1 and T2 are never both available to the assembler, nor are encodings T3 and T4.

<label> The label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset.

Permitted offsets are:

<b>Encoding T1</b>	Even numbers in the range –256 to 254.
<b>Encoding T2</b>	Even numbers in the range –2048 to 2046.
<b>Encoding T3</b>	Even numbers in the range –1048576 to 1048574.
<b>Encoding T4</b>	Even numbers in the range –16777216 to 16777214.
<b>Encoding A1</b>	Multiples of 4 in the range –33554432 to 33554428.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BranchWritePC(PC + imm32);
```

## F7.1.19 BFC

Bit Field Clear clears any number of adjacent bits at any position in a register, without affecting the other bits in the register.

### Encoding T1 ARMv6T2, ARMv7

BFC<c> <Rd>, #<lsb>, #<width>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	(0)	1	1	0	1	1	0	1	1	1	1	0	imm3		Rd		imm2	(0)					msb				

```
d = UInt(Rd); msbit = UInt(msb); lsbbit = UInt(imm3:imm2);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

### Encoding A1 ARMv6T2, ARMv7

BFC<c> <Rd>, #<lsb>, #<width>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	1	1	1	1	1	0	msb			Rd			lsb			0	0	1	1	1	1	1							

```
d = UInt(Rd); msbit = UInt(msb); lsbbit = UInt(lsb);
if d == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *BFC* on page AppxA-4702.

### Assembler syntax

BFC{<c>}{<q>} <Rd>, #<lsb>, #<width>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<lsb> The least significant bit that is to be cleared, in the range 0 to 31. This determines the required value of lsbbit.

<width> The number of bits to be cleared, in the range 1 to 32-<lsb>. The required value of msbit is <lsb>+<width>-1.

### Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  if msbit >= lsbbit then
    R[d]<msbit:lsbbit> = Replicate('0', msbit-lsbbit+1);
    // Other bits of R[d] are unchanged
  else
    UNPREDICTABLE;
```

## F7.1.20 BFI

Bit Field Insert copies any number of low order bits from a register into the same number of adjacent bits at any position in the destination register.

### Encoding T1 ARMv6T2, ARMv7

BFI<c> <Rd>, <Rn>, #<lsb>, #<width>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	(0)	1	1	0	1	1	0	Rn			0	imm3			Rd			imm2(0)			msb						

```

if Rn == '1111' then SEE BFC;
d = UInt(Rd); n = UInt(Rn); msbit = UInt(msb); lsbit = UInt(imm3:imm2);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
  
```

### Encoding A1 ARMv6T2, ARMv7

BFI<c> <Rd>, <Rn>, #<lsb>, #<width>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	1	1	1	1	1	0	msb			Rd			lsb			0	0	1	Rn										

```

if Rn == '1111' then SEE BFC;
d = UInt(Rd); n = UInt(Rn); msbit = UInt(msb); lsbit = UInt(1sb);
if d == 15 then UNPREDICTABLE;
  
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [BFI on page AppxA-4703](#).

### Assembler syntax

BFI{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register.
- <Rn> The source register.
- <lsb> The least significant destination bit, in the range 0 to 31. This determines the required value of 1sb it.
- <width> The number of bits to be copied, in the range 1 to 32-<lsb>. The required value of msbit is <lsb>+<width>-1.

### Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if msbit >= lsbit then
        R[d]<msbit:lsbit> = R[n]<(msbit-lsbit):0>;
        // Other bits of R[d] are unchanged
    else
        UNPREDICTABLE;
  
```

### F7.1.21 BIC (immediate)

Bitwise Bit Clear (immediate) performs a bitwise AND of a register value and the complement of an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

#### Encoding T1 ARMv6T2, ARMv7

BIC{S}<c> <Rd>, <Rn>, #<const>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	i	0	0	0	0	1	S	Rn				0	imm3			Rd			imm8								

```
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1');
(imm32, carry) = ThumbExpandImm_C(i:imm3:imm8, APSR.C);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

#### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

BIC{S}<c> <Rd>, <Rn>, #<const>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	1	1	1	1	0	S	Rn				Rd				imm12													

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1');
(imm32, carry) = ARMEExpandImm_C(imm12, APSR.C);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

BIC{S}{<c>}{<q>} {<Rd>}, <Rn>, #<const>

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>     See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>        The destination register. If S is specified and <Rd> is the PC, see [SUBS PC, LR and related instructions \(T32\) on page F7-3066](#) or [SUBS PC, LR and related instructions \(A32\) on page F7-3068](#).  
In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
- <Rn>        The register that contains the operand. The PC can be used in A32 instructions.
- <const>     The immediate value to be bitwise inverted and ANDed with the value obtained from <Rn>. See [Modified immediate constants in T32 instructions on page F3-2444](#) or [Modified immediate constants in A32 instructions on page F4-2472](#) for the range of values.

The pre-UAL syntax BIC<c>S is equivalent to BICS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND NOT(imm32);
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

## F7.1.22 BIC (register)

Bitwise Bit Clear (register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

### Encoding T1 ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

BICS <Rdn>, <Rm> Outside IT block.

(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

BIC{S}{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift>}

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>      See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>        The destination register. If S is specified and <Rd> is the PC, see [SUBS PC, LR and related instructions \(T32\) on page F7-3066](#) or [SUBS PC, LR and related instructions \(A32\) on page F7-3068](#).  
In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
- <Rn>        The first operand register. The PC can be used in A32 instructions.
- <Rm>        The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.
- <shift>      The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. [Shifts applied to a register on page F2-2419](#) describes the shifts and how they are encoded.

The pre-UAL syntax BIC<c>S is equivalent to BICS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] AND NOT(shifted);
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

## F7.1.23 BIC (register-shifted register)

Bitwise Bit Clear (register-shifted register) performs a bitwise AND of a register value and the complement of a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

BIC{S}<C> <Rd>, <Rn>, <Rm>, <type> <Rs>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	0	1	1	1	0	S	Rn			Rd			Rs			0	type		1	Rm							

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

BIC{S}{<C>}{<q>} {<Rd>,<Rn>, <Rm>, <type> <Rs>

where:

S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<C>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<Rn> The first operand register.

<Rm> The register that is shifted and used as the second operand.

<type> The type of shift to apply to the value read from <Rm>. It must be one of:

ASR Arithmetic shift right, encoded as type = 0b10.

LSL Logical shift left, encoded as type = 0b00.

LSR Logical shift right, encoded as type = 0b01.

ROR Rotate right, encoded as type = 0b11.

<Rs> The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax BIC<C>S is equivalent to BICS<C>.

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] AND NOT(shifted);
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        // APSR.V unchanged
```

## F7.1.24 BKPT

Breakpoint causes a software breakpoint to occur.

Breakpoint is always unconditional, even when inside an IT block.

**Encoding T1** ARMv5T\*, ARMv6\*, ARMv7

BKPT #<imm8>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	1	1	0	imm8							

imm16 = ZeroExtend(imm8, 16);

**Encoding A1** ARMv5T\*, ARMv6\*, ARMv7

BKPT #<imm16>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	0	1	0	0	1	0	imm12												0	1	1	1	imm4					

imm16 = imm12:imm4;

if cond != '1110' then UNPREDICTABLE; // BKPT must be encoded with AL condition

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *BKPT* on page AppxA-4703.

### Assembler syntax

BKPT{<q>} {#}<imm>

where:

<q> See [Standard assembler syntax fields on page F2-2415](#). A BKPT instruction must be unconditional.

<imm> Specifies a value that is stored in the instruction, in the range 0-255 for a T32 instruction or 0-65535 for an A32 instruction. This value is ignored by the PE, but can be used by a debugger to store more information about the breakpoint.

### Operation

```
EncodingSpecificOperations();
AArch32.BKPTInstrDebugEvent(imm16);
```

## F7.1.25 BL, BLX (immediate)

Branch with Link calls a subroutine at a PC-relative address.

Branch with Link and Exchange Instruction Sets (immediate) calls a subroutine at a PC-relative address, and changes instruction set from A32 to T32, or from T32 to A32.

**Encoding T1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7 if J1 == J2 == 1

1	1	1	1	1	0	1	H	imm24																							

imm32 = SignExtend(imm24:H:'0', 32); targetInstrSet = InstrSet\_T32;

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

BL{X}{<c>}{<q>} <label>

where:

- <c>, <q> See *Standard assembler syntax fields on page F2-2415*. An A32 BLX (immediate) instruction must be unconditional.
- X If present, specifies a change of instruction set (from A32 to T32 or from T32 to A32). If X is omitted, the PE remains in the same state.
- <label> The label of the instruction that is to be branched to.
- BL uses encoding T1 or A1. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding with imm32 set to that offset.
- BLX uses encoding T2 or A2. The assembler calculates the required value of the offset from the Align(PC, 4) value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset.
- Permitted offsets are:
- |                    |  |
|--------------------|--|
| <b>Encoding T1</b> | Even numbers in the range –16777216 to 16777214.   |
| <b>Encoding T2</b> | Multiples of 4 in the range –16777216 to 16777212. |
| <b>Encoding A1</b> | Multiples of 4 in the range –33554432 to 33554428. |
| <b>Encoding A2</b> | Even numbers in the range –33554432 to 33554430.   |

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentInstrSet() == InstrSet_A32 then
        LR = PC - 4;
    else
        LR = PC<31:1> : '1';
    if targetInstrSet == InstrSet_A32 then
        targetAddress = Align(PC,4) + imm32;
    else
        targetAddress = PC + imm32;
    SelectInstrSet(targetInstrSet);
    BranchWritePC(targetAddress);
```

## F7.1.26 BLX (register)

Branch with Link and Exchange (register) calls a subroutine at an address and instruction set specified by a register.

**Encoding T1** ARMv5T\*, ARMv6\*, ARMv7

BLX<c> <Rm>

Outside or last in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	1	1	1	1	Rm				(0)	(0)	(0)

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

**Encoding A1** ARMv5T\*, ARMv6\*, ARMv7

BLX<c> <Rm>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	0	1	0	0	1	0	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	0	0	1	1	Rm			

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

BLX{<c>}{<q>} <Rm>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rm> The register that contains the branch target address and instruction set selection bit. This register can be the SP in both A32 and T32 instructions, but ARM deprecates this use of the SP.

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    target = R[m];
    if CurrentInstrSet() == InstrSet_A32 then
        next_instr_addr = PC - 4;
        LR = next_instr_addr;
    else
        next_instr_addr = PC - 2;
        LR = next_instr_addr<31:1> : '1';
    BXWritePC(target);
```

## F7.1.27 BX

Branch and Exchange causes a branch to an address and instruction set specified by a register.

**Encoding T1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

BX<c> <Rm>

Outside or last in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	1	1	1	0	Rm				(0)	(0)	(0)

m = UInt(Rm);  
 if InITBlock() && !LastInITBlock() then UNPREDICTABLE;

**Encoding A1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

BX<c> <Rm>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	0	1	0	0	1	0	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	0	0	0	1	Rm			

m = UInt(Rm);

For information about the CONstrained UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

BX{<c>}{<q>} <Rm>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rm> The register that contains the branch target address and instruction set selection bit. This can be the PC. This register can be the SP in both A32 and T32 instructions, but ARM deprecates this use of the SP.

#### Note

If <Rm> is the PC in a T32 instruction at a non word-aligned address, it results in UNPREDICTABLE behavior because the address passed to the BXWritePC() pseudocode function has bits<1:0> = '10'.

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BXWritePC(R[m]);
```

## F7.1.28 BXJ

In ARMv8, BXJ behaves as a BX instruction, see [BX on page F7-2579](#). This means it causes a branch to an address and instruction set specified by a register.

### Encoding T1 ARMv6T2, ARMv7

BXJ<c> <Rm>

Outside or last in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	1	0	0	Rm				1	0	(0)	0	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

### Encoding A1 ARMv5TEJ, ARMv6\*, ARMv7

BXJ<c> <Rm>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	0	1	0	0	1	0	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	0	0	1	0	Rm			

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

BXJ{<c>}{<q>} <Rm>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rm> The register that specifies the branch target address and instruction set selection bit.

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BXWritePC(R[m]);
```

## F7.1.29 CBNZ, CBZ

Compare and Branch on Nonzero and Compare and Branch on Zero compare the value in a register with zero, and conditionally branch forward a constant value. They do not affect the condition flags.

### Encoding T1 ARMv6T2, ARMv7

CB{N}Z <Rn>, <label>

Not permitted in IT block.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	op	0	i	1	imm5					Rn		

```
n = UInt(Rn); imm32 = ZeroExtend(i:imm5:'0', 32); nonzero = (op == '1');
if InITBlock() then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

CB{N}Z{<q>} <Rn>, <label>

where:

- N If specified, causes the branch to occur when the contents of <Rn> are nonzero (encoded as op = 1). If omitted, causes the branch to occur when the contents of <Rn> are zero (encoded as op = 0).
- <q> See [Standard assembler syntax fields on page F2-2415](#). A CBZ or CBNZ instruction must be unconditional.
- <Rn> The operand register.
- <label> The label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the CBZ or CBNZ instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range 0 to 126.

### Operation

```
EncodingSpecificOperations();
if nonzero != IsZero(R[n]) then
  BranchWritePC(PC + imm32);
```

### F7.1.30 CDP, CDP2

Coprocessor Data Processing is a generic coprocessor instruction. None of the fields have any functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1`, `opc2`, `CRd`, `CRn`, and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid CDP and CDP2 instructions when `coproc` is in the range p8-p15. For more information see [Coprocessor support on page E1-2331](#).

**Encoding T1/A1** ARMv6T2, ARMv7 for encoding T1  
 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7 for encoding A1

CDP<c> <coproc>, <opc1>, <CRd>, <CRn>, <CRm>, <opc2>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1 1 1 0				opc1				CRn		CRd		coproc		opc2		0	CRm										

if `coproc == '101x'` then SEE "Floating-point instructions";  
`cp = UInt(coproc);`

**Encoding T2/A2** ARMv6T2, ARMv7 for encoding T2  
 ARMv5T\*, ARMv6\*, ARMv7 for encoding A2

CDP2<c> <coproc>, <opc1>, <CRd>, <CRn>, <CRm>, <opc2>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	0	opc1				CRn		CRd		coproc		opc2		0	CRm										

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1 1 1 1				1 1 1 0				opc1				CRn		CRd		coproc		opc2		0	CRm										

if `coproc == '101x'` then SEE "Floating-point instructions";  
`cp = UInt(coproc);`

**Floating-point instructions** See [Floating-point data-processing instructions on page F5-2511](#)

## Assembler syntax

CDP{2}{<c>}{<q>} <coproc>, {#}<opc1>, <CRd>, <CRn>, <CRm> {, {#}<opc2>}

where:

- 2 If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 CDP2 instruction must be unconditional.
- <coproc> The name of the coprocessor, and causes the corresponding coprocessor number to be placed in the cp\_num field of the instruction. The generic coprocessor names are p0-p15.
- <opc1> Is a coprocessor-specific opcode, in the range 0 to 15.
- <CRd> The destination coprocessor register for the instruction.
- <CRn> The coprocessor register that contains the first operand.
- <CRm> The coprocessor register that contains the second operand.
- <opc2> Is a coprocessor-specific opcode in the range 0 to 7. If it is omitted, <opc2> is 0.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Cproc_Accepted(cp, ThisInstr()) then
        GenerateCoproprocessorException();
    else
        Cproc_InternalOperation(cp, ThisInstr());
```

## F7.1.31 CLREX

Clear-Exclusive clears the local monitor of the executing PE.

### Encoding T1 ARMv7

CLREX<c>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

// No additional decoding required

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

CLREX{<c>}{<q>}

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 CLREX instruction must be unconditional.

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    ClearExclusiveLocal(ProcessorID());
```

## F7.1.32 CLZ

Count Leading Zeros returns the number of binary zero bits before the first binary one bit in a value.

### Encoding T1 ARMv6T2, ARMv7

CLZ<c> <Rd>, <Rm>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

cond		0	0	0	1	0	1	1	0	(1)	(1)	(1)	(1)	Rd				(1)	(1)	(1)	(1)	0	0	0	1	Rm					

```

d = UInt(Rd); m = UInt(Rm);
if d == 15 || m == 15 then UNPREDICTABLE;
    
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *CLZ* on page AppxA-4703.

### Assembler syntax

CLZ{<c>}{<q>} <Rd>, <Rm>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<Rm> The register that contains the operand. Its number must be encoded twice in encoding T1.

### Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    result = CountLeadingZeroBits(R[m]);
    R[d] = result<31:0>;
    
```

### F7.1.33 CMN (immediate)

Compare Negative (immediate) adds a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

#### Encoding T1 ARMv6T2, ARMv7

CMN<c> <Rn>, #<const>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	i	0	1	0	0	0	1	Rn				0	imm3			1	1	1	1	imm8							

n = UInt(Rn); imm32 = ThumbExpandImm(i:imm3:imm8);  
 if n == 15 then UNPREDICTABLE;

#### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

CMN<c> <Rn>, #<const>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	1	1	0	1	1	1	Rn			(0)	(0)	(0)	(0)	imm12														

n = UInt(Rn); imm32 = ARMEExpandImm(imm12);

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

#### Assembler syntax

CMN{<c>}{<q>} <Rn>, #<const>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rn> The register that contains the operand. SP can be used in T32 and A32 instructions. The PC can be used in A32 instructions.
- <const> The immediate value to be added to the value obtained from <Rn>. See [Modified immediate constants in T32 instructions on page F3-2444](#) or [Modified immediate constants in A32 instructions on page F4-2472](#) for the range of values.

#### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcV) = AddWithCarry(R[n], imm32, '0');
    APSR.<N,Z,C,V> = nzcV;
```

## F7.1.34 CMN (register)

Compare Negative (register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

**Encoding T1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

CMN<c> <Rn>, <Rm>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	0	1	0	1	1	Rm			Rn		

n = UInt(Rn); m = UInt(Rm);  
 (shift\_t, shift\_n) = (SRTYPE\_LSL, 0);

**Encoding T2** ARMv6T2, ARMv7

CMN<c>.W <Rn>, <Rm>{, <shift>}

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	1	1	0	0	0	1	Rn			(0)	imm3			1	1	1	1	imm2		type	Rm					

n = UInt(Rn); m = UInt(Rm);  
 (shift\_t, shift\_n) = DecodeImmShift(type, imm3:imm2);  
 if n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

CMN<c> <Rn>, <Rm>{, <shift>}

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	0	1	0	1	1	1	Rn			(0)	(0)	(0)	(0)	imm5				type		0	Rm						

n = UInt(Rn); m = UInt(Rm);  
 (shift\_t, shift\_n) = DecodeImmShift(type, imm5);

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

CMN{<c>}{<q>} <Rn>, <Rm> {, <shift>}

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rn> The first operand register. SP can be used in T32 instructions (encoding T2) and in A32 instructions. The PC can be used in A32 instructions.
- <Rm> The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.
- <shift> The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. [Shifts applied to a register on page F2-2419](#) describes the shifts and how they are encoded.

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, nzcvc) = AddWithCarry(R[n], shifted, '0');
    APSR.<N,Z,C,V> = nzcvc;
```

### F7.1.35 CMN (register-shifted register)

Compare Negative (register-shifted register) adds a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7  
 CMN<c> <Rn>, <Rm>, <type> <Rs>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	0	1	0	1	1	1	Rn				(0)(0)(0)(0)				Rs		0	type		1	Rm							

```
n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

#### Assembler syntax

CMN{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rn> The first operand register.
- <Rm> The register that is shifted and used as the second operand.
- <type> The type of shift to apply to the value read from <Rm>. It must be one of:
  - ASR Arithmetic shift right, encoded as type = 0b10.
  - LSL Logical shift left, encoded as type = 0b00.
  - LSR Logical shift right, encoded as type = 0b01.
  - ROR Rotate right, encoded as type = 0b11.
- <Rs> The register whose bottom byte contains the amount to shift by.

#### Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  shift_n = UInt(R[s]<7:0>);
  shifted = Shift(R[m], shift_t, shift_n, APSR.C);
  (result, nzc) = AddWithCarry(R[n], shifted, '0');
  APSR.<N,Z,C,V> = nzc;
```

## F7.1.36 CMP (immediate)

Compare (immediate) subtracts an immediate value from a register value. It updates the condition flags based on the result, and discards the result.

**Encoding T1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

CMP<c> <Rn>, #<imm8>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	1	Rn			imm8							

n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);

**Encoding T2** ARMv6T2, ARMv7

 if n == 15 then UNPREDICTABLE;

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

CMP<c> <Rn>, #<const>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	1	1	0	1	0	1	Rn			(0)	(0)	(0)	(0)	imm12														

n = UInt(Rn); imm32 = ARMEExpandImm(imm12);

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

CMP{<c>}{<q>} <Rn>, #<const>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rn> The first operand register. SP can be used in T32 instructions (encoding T2) and in A32 instructions. The PC can be used in A32 instructions.

<const> The immediate value to be compared with the value obtained from <Rn>. The range of values is 0-255 for encoding T1. See [Modified immediate constants in T32 instructions on page F3-2444](#) or [Modified immediate constants in A32 instructions on page F4-2472](#) for the range of values for encoding T2 and A1.

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcvc) = AddWithCarry(R[n], NOT(imm32), '1');
    APSR.<N,Z,C,V> = nzcvc;
```

### F7.1.37 CMP (register)

Compare (register) subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

#### Encoding T1 ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

CMP<c> <Rn>, <Rm> <Rn> and <Rm> both from R0-R7

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

n = UInt(Rn); m = UInt(Rm);  
 (shift\_t, shift\_n) = DecodeImmShift(type, imm3:imm2);  
 if n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

#### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

CMP<c> <Rn>, <Rm>{, <shift>}

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	0	1	0	1	0	1	Rn			(0)	(0)	(0)	(0)	imm5			type	0	Rm								

n = UInt(Rn); m = UInt(Rm);  
 (shift\_t, shift\_n) = DecodeImmShift(type, imm5);

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [CMP \(register\)](#) on page AppxA-4703.

## Assembler syntax

CMP{<c>}{<q>} <Rn>, <Rm> {, <shift>}

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rn> The first operand register. The SP can be used. The PC can be used in A32 instructions.
- <Rm> The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions. The SP can be used in both A32 and T32 instructions, but:
- ARM deprecates the use of SP.
  - When assembling for the T32 instruction set, only encoding T2 is available.
- <shift> The shift to apply to the value read from <Rm>. If present, encodings T1 and T2 are not permitted. If absent, no shift is applied and all encodings are permitted. [Shifts applied to a register on page F2-2419](#) describes the shifts and how they are encoded.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, nzc) = AddWithCarry(R[n], NOT(shifted), '1');
    APSR.<N,Z,C,V> = nzc;
```

### F7.1.38 CMP (register-shifted register)

Compare (register-shifted register) subtracts a register-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

#### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

CMP<c> <Rn>, <Rm>, <type> <Rs>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	0	1	0	1	0	1	Rn			(0)(0)(0)(0)				Rs		0	type		1	Rm							

```
n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

#### Assembler syntax

CMP{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rn> The first operand register.
- <Rm> The register that is shifted and used as the second operand.
- <type> The type of shift to apply to the value read from <Rm>. It must be one of:
  - ASR Arithmetic shift right, encoded as type = 0b10.
  - LSL Logical shift left, encoded as type = 0b00.
  - LSR Logical shift right, encoded as type = 0b01.
  - ROR Rotate right, encoded as type = 0b11.
- <Rs> The register whose bottom byte contains the amount to shift by.

#### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, nzcvc) = AddWithCarry(R[n], NOT(shifted), '1');
    APSR.<N,Z,C,V> = nzcvc;
```

**F7.1.39 CPS**

Change PE State is a system instruction, see [CPS \(T32\) on page F7-3034](#) and [CPS \(A32\) on page F7-3036](#).

**F7.1.40 CPY**

Copy is a pre-UAL synonym for MOV (register). See [MOV \(register, T32\) on page F7-2710](#) and [MOV \(register, A32\) on page F7-2712](#).

**Assembler syntax**

CPY <Rd>, <Rn>

This is equivalent to:

MOV <Rd>, <Rn>

## F7.1.41 CRC32, CRC32C

CRC32 performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It is an OPTIONAL instruction, introduced in ARMv8. It performs a CRC on an input value that can be 8, 16, or 32 bits, taking an input CRC value from a second register, and returning the output CRC value to the that supplied the input CRC. To align with common usage, the bit order of the values is reversed as part of the operation, and:

- The CRC32 form of the instruction uses the polynomial 0x04C11DB7 for the CRC calculation.
- The CRC32C form of the instruction uses the polynomial 0x1EDC6F41 for the CRC calculation.

———— **Note** —————

[ID\\_ISAR5](#).CRC32 indicates whether this instruction is supported in the T32 and A32 instruction sets.

### Encoding T1 ARMv8

CRC32{C}<y> Rd, Rn, Rm

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	0	1	1	0	C		Rn			1	1	1	1		Rd		1	0	sz		Rm				

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
size = 8 << UInt(sz);
crc32c = (C == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if size == 64 then UNPREDICTABLE;
if InITBlock() then UNPREDICTABLE;
```

### Encoding A1 ARMv8

CRC32{C}<y><c> Rd, Rn, Rm

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	0	1	0	sz	0		Rn		Rd	(0)	(0)	C	(0)	0	1	0	0											Rm

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
size = 8 << UInt(sz);
crc32c = (C == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if size == 64 then UNPREDICTABLE;
if cond != '1110' then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [CRC32, CRC32C on page AppxA-4704](#).

## Assembler syntax

CRC32{C}<y><c> Rd, Rn, Rm

where:

- C           Specified the polynomial to be used for the CRC calculation:
- If C is omitted, the calculation uses the polynomial 0x04C11DB7.
  - If C is included, the calculation uses the polynomial 0x1EDC6F41.
- <y>           Is one of:
- B           Specifies that the instruction takes a byte of new data, encoded as sz = '00'.
- H           Specifies that the instruction takes a halfword of new data, encoded as sz = '01'.
- H           Specifies that the instruction takes a word of new data, encoded as sz = '10'.
- <c>           See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>         The destination register for the output CRC value.
- <Rn>         The first operand register, that holds the input CRC value.
- <Rm>         The second operand register, that holds the data that the CRC is to be performed on.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    acc = R[n];           // accumulator
    val = R[m]<size-1:0>; // input value
    poly = (if crc32c then 0x1EDC6F41 else 0x04C11DB7)<31:0>;
    tempacc = BitReverse(acc):Zeros(size);
    tempval = BitReverse(val):Zeros(32);
    // Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
    R[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

## F7.1.42 DBG

Debug Hint provides a hint to debug and related systems. See their documentation for what use (if any) they make of this instruction.

### Encoding T1 ARMv7 (executes as NOP in ARMv6T2)

DBG<c> #<option>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

// Any decoding of 'option' is specified by the debug system

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

DBG{<c>}{<q>} #<option>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<option> Provides extra information about the hint, and is in the range 0 to 15.

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    Hint_Debug(option);
```

## F7.1.43 DCPS1, DCPS2, DCPS3

DCPS<sub>x</sub> allows the debugger to move the PE into a higher Exception Level or to a specific mode at the current Exception Level.

DCPS<sub>x</sub> is always UNDEFINED in Non-debug state.

For more information see *DCPS* on page H2-4351.

### Encoding T1 ARMv8

DCPS<opt>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	1	1	1	0	0	0	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	opt	

if !Halted() || opt == '00' then UNDEFINED;

### Assembler syntax

DCPS<opt>

where:

<opt> Specifies the target Exception Level and the mode the PE enters.

Is one of:

- 1 The target Exception Level is EL1 and:
  - If EL1 is using AArch32, the PE enters SVC mode.

**Note**

If EL3 is using AArch32, Secure SVC mode is an EL3 mode. This means DCPS1 causes the PE to enter EL3.

  - If EL1 is using AArch64, the PE enters EL1h, and executes future instructions as A64 instructions.

Encoded as opt = 01.
- 2 The target Exception Level is EL2 and:
  - If EL2 is using AArch32, the PE enters Hyp mode.
  - If EL2 is using AArch64, the PE enters EL2h, and executes future instructions as A64 instructions.

Encoded as opt = 10.
- 3 The target Exception Level is EL3 and:
  - If EL3 is using AArch32, the PE enters Monitor mode.
  - If EL3 is using AArch64, the PE enters EL3h, and executes future instructions as A64 instructions.

Encoded as opt = 11.

### Operation

DCPSInstruction(opt);

## F7.1.44 DMB

Data Memory Barrier is a memory barrier that ensures the ordering of observations of memory accesses, see [Data Memory Barrier \(DMB\) on page E2-2353](#).

### Encoding T1 ARMv7

DMB<c> <option>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	1	(1)	(1)	(1)	(1)	1	0	(0)	0	(1)	(1)	(1)	(1)	0	1	0	1	option			

// No additional decoding required

### Encoding A1 ARMv7

DMB <option>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	0	1	0	1	1	1	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	1	0	1	option		

// No additional decoding required

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

DMB{<c>}{<q>} {<option>}

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 DMB instruction must be unconditional.

<option> Specifies an optional limitation on the DMB operation. Values are:

SY	Full system is the required shareability domain, reads and writes are the required access types. Can be omitted. This option is referred to as the full system DMB. Encoded as option = 0b1111.
ST	Full system is the required shareability domain, writes are the required access type. SYST is a synonym for ST. Encoded as option = 0b1110.
LD	Full system is the required shareability domain, reads are the required access type. Encoded as option = 0b1101.
ISH	Inner Shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = 0b1011.
ISHST	Inner Shareable is the required shareability domain, writes are the required access type. Encoded as option = 0b1010.
ISHLD	Inner Shareable is the required shareability domain, reads are the required access type. Encoded as option = 0b1001.
NSH	Non-shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = 0b0111.
NSHST	Non-shareable is the required shareability domain, writes are the required access type. Encoded as option = 0b0110.
NSHLD	Non-shareable is the required shareability domain, reads are the required access type. Encoded as option = 0b0101.
OSH	Outer Shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = 0b0011.

OSHST Outer Shareable is the required shareability domain, writes are the required access type.  
Encoded as option = 0b0010.

OSHLA Outer Shareable is the required shareability domain, reads are the required access type.  
Encoded as option = 0b0001.

All other encodings of option are reserved. It is IMPLEMENTATION DEFINED whether options other than SY are implemented. All unsupported and reserved options must execute as a full system DMB operation, but software must not rely on this behavior.

———— **Note** —————

The instruction supports the following alternative <option> values, but ARM recommends that software does not use these alternative values:

- SH as an alias for ISH.
- SHST as an alias for ISHST.
- UN as an alias for NSH.
- UNST is an alias for NSHST.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    case option of
        when '0001' domain = MBReqDomain_OuterShareable; types = MBReqTypes_Reads;
        when '0010' domain = MBReqDomain_OuterShareable; types = MBReqTypes_Writes;
        when '0011' domain = MBReqDomain_OuterShareable; types = MBReqTypes_All;
        when '0101' domain = MBReqDomain_Nonshareable; types = MBReqTypes_Reads;
        when '0110' domain = MBReqDomain_Nonshareable; types = MBReqTypes_Writes;
        when '0111' domain = MBReqDomain_Nonshareable; types = MBReqTypes_All;
        when '1001' domain = MBReqDomain_InnerShareable; types = MBReqTypes_Reads;
        when '1010' domain = MBReqDomain_InnerShareable; types = MBReqTypes_Writes;
        when '1011' domain = MBReqDomain_InnerShareable; types = MBReqTypes_All;
        when '1101' domain = MBReqDomain_FullSystem; types = MBReqTypes_Reads;
        when '1110' domain = MBReqDomain_FullSystem; types = MBReqTypes_Writes;
        otherwise domain = MBReqDomain_FullSystem; types = MBReqTypes_All;

    if HaveEL(EL2) && !IsSecure() && !CurrentModeIsHyp() then
        if HCR.BSU == '11' then
            domain = MBReqDomain_FullSystem;
        if HCR.BSU == '10' && domain != MBReqDomain_FullSystem then
            domain = MBReqDomain_OuterShareable;
        if HCR.BSU == '01' && domain == MBReqDomain_Nonshareable then
            domain = MBReqDomain_InnerShareable;

    DataMemoryBarrier(domain, types);
```

## F7.1.45 DSB

Data Synchronization Barrier is a memory barrier that ensures the completion of memory accesses, see [Data Synchronization Barrier \(DSB\) on page E2-2354](#).

### Encoding T1 ARMv7

DSB<c> <option>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	1	(1)	(1)	(1)	(1)	1	0	(0)	0	(1)	(1)	(1)	(1)	0	1	0	0	option			

// No additional decoding required

### Encoding A1 ARMv7

DSB <option>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	0	1	0	1	1	1	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	1	0	0	option		

// No additional decoding required

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

DSB{<c>}{<q>} {<option>}

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 DSB instruction must be unconditional.

<option> Specifies an optional limitation on the DSB operation. Values are:

SY	Full system is the required shareability domain, reads and writes are the required access types. Can be omitted. This option is referred to as the full system DSB. Encoded as option = 0b1111.
ST	Full system is the required shareability domain, writes are the required access type. SYST is a synonym for ST. Encoded as option = 0b1110.
LD	Full system is the required shareability domain, reads are the required access type. Encoded as option = 0b1101.
ISH	Inner Shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = 0b1011.
ISHST	Inner Shareable is the required shareability domain, writes are the required access type. Encoded as option = 0b1010.
ISHLD	Inner Shareable is the required shareability domain, reads are the required access type. Encoded as option = 0b1001.
NSH	Non-shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = 0b0111.
NSHST	Non-shareable is the required shareability domain, writes are the required access type. Encoded as option = 0b0110.
NSHLD	Non-shareable is the required shareability domain, reads are the required access type. Encoded as option = 0b0101.
OSH	Outer Shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = 0b0011.

OSHST Outer Shareable is the required shareability domain, writes are the required access type.  
Encoded as option = 0b0010.

OSHLD Outer Shareable is the required shareability domain, reads are the required access type.  
Encoded as option = 0b0001.

All other encodings of option are reserved. It is IMPLEMENTATION DEFINED whether options other than SY are implemented. All unsupported and reserved options must execute as a full system DSB operation, but software must not rely on this behavior.

———— **Note** —————

The instruction supports the following alternative <option> values, but ARM recommends that software does not use these alternative values:

- SH as an alias for ISH.
- SHST as an alias for ISHST.
- UN as an alias for NSH.
- UNST is an alias for NSHST.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    case option of
        when '0001' domain = MBReqDomain_OuterShareable; types = MBReqTypes_Reads;

```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

EOR{S}{<c>}{<q>} {<Rd>}, <Rn>, #<const>

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>      See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>         The destination register. If S is specified and <Rd> is the PC, see [SUBS PC, LR and related instructions \(T32\) on page F7-3066](#) or [SUBS PC, LR and related instructions \(A32\) on page F7-3068](#).  
In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
- <Rn>         The register that contains the operand. The PC can be used in A32 instructions.
- <const>      The immediate value to be exclusive ORed with the value obtained from <Rn>. See [Modified immediate constants in T32 instructions on page F3-2444](#) or [Modified immediate constants in A32 instructions on page F4-2472](#) for the range of values.

The pre-UAL syntax EOR<c>S is equivalent to EORS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] EOR imm32;
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

## F7.1.47 EOR (register)

Bitwise Exclusive OR (register) performs a bitwise Exclusive OR of a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding T1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

EOR{S}{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift>}

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>      See *Standard assembler syntax fields* on page F2-2415.
- <Rd>        The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions (T32)* on page F7-3066 or *SUBS PC, LR and related instructions (A32)* on page F7-3068.
- In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2296.
- <Rn>        The first operand register. The PC can be used in A32 instructions.
- <Rm>        The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.
- <shift>      The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page F2-2419 describes the shifts and how they are encoded.

In T32 assembly:

- Outside an IT block, if EORS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EORS <Rd>, <Rn> had been written
- Inside an IT block, if EOR<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EOR<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax EOR<c>S is equivalent to EORS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] EOR shifted;
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

## F7.1.48 EOR (register-shifted register)

Bitwise Exclusive OR (register-shifted register) performs a bitwise Exclusive OR of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

EOR{S}<C> <Rd>, <Rn>, <Rm>, <type> <Rs>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	0	0	0	0	1	S	Rn			Rd			Rs			0	type		1	Rm							

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

EOR{S}{<C>}{<q>} {<Rd>,<Rn>, <Rm>, <type> <Rs>

where:

S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<C>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<Rn> The first operand register.

<Rm> The register that is shifted and used as the second operand.

<type> The type of shift to apply to the value read from <Rm>. It must be one of:

ASR Arithmetic shift right, encoded as type = 0b10.

LSL Logical shift left, encoded as type = 0b00.

LSR Logical shift right, encoded as type = 0b01.

ROR Rotate right, encoded as type = 0b11.

<Rs> The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax EOR<C>S is equivalent to EORS<C>.

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] EOR shifted;
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
    // APSR.V unchanged
```

## F7.1.49 ERET

Exception Return is a system instruction, see [ERET](#) on page F7-3038.

## F7.1.50 HLT

Halting breakpoint causes a software breakpoint to occur.

Halting breakpoint is always unconditional, even inside an IT block.

### Encoding T1 ARMv8

HLT #<imm8>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	0	1	0	1	0	imm6					

if EDSCR.HDE == '0' || !HaltingAllowed() then UNDEFINED;  
 // imm8 is for assembly/disassembly only and ignored by hardware

### Encoding A1 ARMv8

HLT #<imm16>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	0	0	0	0	imm12										0	1	1	1	imm4					

if EDSCR.HDE == '0' || !HaltingAllowed() then UNDEFINED;  
 if cond != '1110' then UNPREDICTABLE; // HLT must be encoded with AL condition  
 // imm12:imm4 are for assembly/disassembly only and ignored by hardware

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [HLT on page AppxA-4704](#).

### Assembler syntax

HLT{<q>} {#}<imm>

where:

- <q> See [Standard assembler syntax fields on page F2-2415](#). An HLT instruction must be unconditional.
- <imm> Specifies a value that is stored in the instruction, in the range 0-63 for a T32 instruction or 0-65535 for an A32 instruction. This value is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

### Operation

```
EncodingSpecificOperations();
Halt(DebugHalt_HaltInstruction);
```

## F7.1.51 HVC

Hypervisor Call is a system instruction, see [HVC](#) on page F7-3040.

## F7.1.52 ISB

Instruction Synchronization Barrier flushes the pipeline in the PE, so that all instructions following the ISB are fetched from cache or memory, after the instruction has been completed. It ensures that the effects of context changing operations executed before the ISB instruction are visible to the instructions fetched after the ISB. Context changing operations include changing the *Address Space Identifier* (ASID), TLB maintenance operations, branch predictor maintenance operations, and all changes to the System registers. In addition, any branches that appear in program order after the ISB instruction are written into the branch prediction logic with the context that is visible after the ISB instruction. This is needed to ensure correct execution of the instruction stream.

### Encoding T1 ARMv7

ISB<c> <option>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	1	(1)	(1)	(1)	(1)	1	0	(0)	0	(1)	(1)	(1)	(1)	0	1	1	0	option			

// No additional decoding required

### Encoding A1 ARMv7

ISB <option>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	0	1	0	1	1	1	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	1	1	0	option		

// No additional decoding required

For information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

ISB{<c>}{<q>} {<option>}

where:

<c>, <q> See [Standard assembler syntax fields](#) on page F2-2415. An A32 ISB instruction must be unconditional.

<option> Specifies an optional limitation on the ISB operation. Values are:

SY Full system ISB operation, encoded as option = 0b1111. Can be omitted.

All other encodings of option are reserved. The corresponding instructions execute as full system ISB operations, but must not be relied upon by software.

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    InstructionSynchronizationBarrier();
```

## F7.1.53 IT

If-Then makes up to four following instructions (the *IT block*) conditional. The conditions for the instructions in the IT block are the same as, or the inverse of, the condition the IT instruction specifies for the first instruction in the block.

The IT instruction itself does not affect the condition flags, but the execution of the instructions in the IT block can change the condition flags.

16-bit instructions in the IT block, other than `CMP`, `CMN` and `TST`, do not set the condition flags. An IT instruction with the AL condition can change the behavior without conditional execution.

The architecture permits exception return to an instruction in the IT block only if the restoration of the `CPSR` restores `ITSTATE` to a state consistent with the conditions specified by the IT instruction. Any other exception return to an instruction in an IT block is UNPREDICTABLE. Any branch to a target instruction in an IT block is not permitted, and if such a branch is made it is UNPREDICTABLE what condition is used when executing that target instruction and any subsequent instruction in the IT block.

See also [Conditional instructions on page F1-2380](#) and [Conditional execution on page F2-2416](#).

### Encoding T1 ARMv6T2, ARMv7

IT{<x>{<y>{<z>}}} <firstcond>

Not permitted in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	1	1	1	firstcond				mask			

if mask == '0000' then SEE "Related encodings";  
 if firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1) then UNPREDICTABLE;  
 if InITBlock() then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *IT* on page AppxA-4704.

**Related encodings** See [If-Then, and hints on page F3-2441](#).

### Assembler syntax

IT{<x>{<y>{<z>}}}{<q>} <firstcond>

where:

- <x> The condition for the second instruction in the IT block.
- <y> The condition for the third instruction in the IT block.
- <z> The condition for the fourth instruction in the IT block.
- <q> See [Standard assembler syntax fields on page F2-2415](#). An IT instruction must be unconditional.
- <firstcond> The condition for the first instruction in the IT block. See [Table F2-1 on page F2-2416](#) for the range of conditions available, and the encodings.

Each of <x>, <y>, and <z> can be either:

- T Then. The condition for the instruction is <firstcond>.
- E Else. The condition for the instruction is the inverse of <firstcond>. The condition code is the same as <firstcond>, except that the least significant bit is inverted. E must not be specified if <firstcond> is AL.

[Table F7-1 on page F7-2611](#) shows how the values of <x>, <y>, and <z> determine the value of the mask field.

**Table F7-1 Determination of mask field**

<x>	<y>	<z>	mask[3]	mask[2]	mask[1]	mask[0]
Omitted	Omitted	Omitted	1	0	0	0
T	Omitted	Omitted	firstcond[0]	1	0	0
E	Omitted	Omitted	NOT firstcond[0]	1	0	0
T	T	Omitted	firstcond[0]	firstcond[0]	1	0
E	T	Omitted	NOT firstcond[0]	firstcond[0]	1	0
T	E	Omitted	firstcond[0]	NOT firstcond[0]	1	0
E	E	Omitted	NOT firstcond[0]	NOT firstcond[0]	1	0
T	T	T	firstcond[0]	firstcond[0]	firstcond[0]	1
E	T	T	NOT firstcond[0]	firstcond[0]	firstcond[0]	1
T	E	T	firstcond[0]	NOT firstcond[0]	firstcond[0]	1
E	E	T	NOT firstcond[0]	NOT firstcond[0]	firstcond[0]	1
T	T	E	firstcond[0]	firstcond[0]	NOT firstcond[0]	1
E	T	E	NOT firstcond[0]	firstcond[0]	NOT firstcond[0]	1
T	E	E	firstcond[0]	NOT firstcond[0]	NOT firstcond[0]	1
E	E	E	NOT firstcond[0]	NOT firstcond[0]	NOT firstcond[0]	1

The conditions specified in an IT instruction must match those specified in the syntax of the instructions in its IT block. When assembling to A32 code, assemblers check IT instruction syntax for validity but do not generate assembled instructions for them. See [Conditional instructions on page F1-2380](#).

## Operation

```
EncodingSpecificOperations();
ITSTATE.IT<7:0> = firstcond:mask;
```

## F7.1.54 LDA

Load Acquire Word loads a word from memory and writes it to a register. The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#) on page E2-2355

For more information about support for shared memory see [Synchronization and semaphores](#) on page E2-2369. For information about memory accesses see [Memory accesses](#) on page F2-2422.

    acctype = AccType_ORDERED;
    aligned = TRUE;
    R[t] = ZeroExtend(MemA_with_type[address, 4, acctype, aligned], 32);
    
```

## F7.1.56 LDAEX

Load-Acquire Exclusive Word loads a word from memory, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2355.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2369. For information about memory accesses see *Memory accesses* on page F2-2422.

```

### F7.1.61 LDC, LDC2 (immediate)

Load Coprocessor loads memory data from a sequence of consecutive memory addresses to a conceptual coprocessor. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the D bit, the CRd field, and in the Unindexed addressing mode only, the imm8 field. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid LDC and LDC2 instructions when coproc is in the range p8-p15. For more information see [Coprocesor support on page E1-2331](#).

In an implementation that includes EL2, the permitted LDC access to a system control register can be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [Trapping general CP14 accesses to debug registers on page G1-3515](#).

———— **Note** —————

For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

 if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet\_A32) then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDC/LDC2 \(literal\) on page AppxA-4704](#).

**Advanced SIMD and floating-point** See [Extension register load/store instructions on page F5-2514](#)

## Assembler syntax

LDC{2}{L}{<c>}{<q>}	<coproc>, <CRd>, <label>	Normal form with P = 1, W = 0
LDC{2}{L}{<c>}{<q>}	<coproc>, <CRd>, [PC, #+/-<imm>]	Alternative form with P = 1, W = 0
LDC{2}{L}{<c>}{<q>}	<coproc>, <CRd>, [PC], <option>	Unindexed form with P = 0, U = 1, W = 0, encoding A1/A2 only

where:

2	If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
L	If specified, selects the D == 1 form of the encoding. If omitted, selects the D == 0 form.
<c>, <q>	See <a href="#">Standard assembler syntax fields on page F2-2415</a> . An A32 LDC2 instruction must be unconditional.
<coproc>	The name of the coprocessor. The generic coprocessor names are p0-p15.
<CRd>	The coprocessor destination register.
<label>	The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE (encoded as U == 1). If the offset is negative, imm32 is equal to minus the offset and add == FALSE (encoded as U == 0).

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2380](#).

The unindexed form is permitted for the A32 instruction set only. In it, <option> is a coprocessor option, written as an integer 0-255 enclosed in { } and encoded in imm8.

The pre-UAL syntax LDC<c>L is equivalent to LDCL<c>.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coprocc_Accepted(cp, ThisInstr()) then
        GenerateCoproccorException();
    else
        NullCheckIfThumbEE(15);
        offset_addr = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
        address = if index then offset_addr else Align(PC,4);
        repeat
            Coproc_SendLoadedWord(MemA[address,4], cp, ThisInstr());
            address = address + 4;
        until Coproc_DoneLoading(cp, ThisInstr());
  
```

### F7.1.63 LDM/LDMIA/LDMFD (T32)

Load Multiple Increment After (Load Multiple Full Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the highest of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address. Related system instructions are *LDM (User registers)* on page F7-3044 and *LDM (exception return)* on page F7-3042.

**Encoding T1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7 (not in ThumbEE)

if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *LDM/LDMIA/LDMFD (T32)* on page AppxA-4705.

**ThumbEE instructions** ARM deprecates any use of ThumbEE instructions and they are not documented in this manual.

## Assembler syntax

LDM{<c>}{<q>} <Rn>{!}, <registers>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rn> The base register. SP can be used. If it is the SP and ! is specified, the instruction is treated as described in [POP \(T32\) on page F7-2756](#).

! Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1. If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.

<registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2426](#).

Encoding T2 does not support a list containing only one register. If an LDMIA instruction with just one register <Rt> in the list is assembled to T32 and encoding T1 is not available, it is assembled to the equivalent LDR{<c>}{<q>} <Rt>, [<Rn>]{, #4} instruction.

The SP cannot be in the list.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#). If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

If ! is specified, <registers> cannot include the base register.

LDMIA and LDMFD are pseudo-instructions for LDM. LDMFD refers to its use for popping data from Full Descending stacks.

The pre-UAL syntaxes LDM<c>IA and LDM<c>FD are equivalent to LDM<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4];  address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

## F7.1.64 LDM/LDMIA/LDMFD (A32)

Load Multiple Increment After (Load Multiple Full Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the highest of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address. Related system instructions are [LDM \(User registers\)](#) on page F7-3044 and [LDM \(exception return\)](#) on page F7-3042.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

LDM<c> <Rn>{!}, <registers>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1	0	0	0	1	0	W	1	Rn				register_list															

```

if W == '1' && Rn == '1101' && BitCount(register_list) > 1 then SEE POP (ARM);
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
    
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDM/LDMIA/LDMFD \(A32\)](#) on page AppxA-4705.

## Assembler syntax

LDM{<c>}{<q>} <Rn>{!}, <registers>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rn> The base register. SP can be used. If the SP is used, ! is specified, and there is more than one register in the <registers> list, the instruction is treated as described in [POP \(A32\) on page F7-2758](#).
- ! Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1. If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.
- <registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2426](#).
- The SP can be in the list. However, ARM deprecates using these instructions with SP in the list.
- The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
- ARM deprecates using these instructions with both the LR and the PC in the list.

LDMIA and LDMFD are pseudo-instructions for LDM. LDMFD refers to its use for popping data from Full Descending stacks.

The pre-UAL syntaxes LDM<c>IA and LDM<c>FD are equivalent to LDM<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4]; address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

## F7.1.65 LDMDA/LDMFA

Load Multiple Decrement After (Load Multiple Full Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address.

Related system instructions are [LDM \(User registers\) on page F7-3044](#) and [LDM \(exception return\) on page F7-3042](#).

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7  
 LDMDA<c> <Rn>{!}, <registers>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		1	0	0	0	0	0	W	1	Rn				register_list																	

```
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDMDA/LDMFA on page AppxA-4706](#).

## Assembler syntax

LMDMA{<c>}{<q>} <Rn>{!}, <registers>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rn> The base register. SP can be used.

! Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1.  
If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.

<registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2426](#).

The SP can be in the list. However, instructions that include the SP in the list are deprecated.

The PC can be in the list. If it is, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).

Instructions that include both the LR and the PC in the list are deprecated.

LDMFA is a pseudo-instruction for LMDMA, referring to its use for popping data from Full Ascending stacks.

The pre-UAL syntaxes LDM<c>DA and LDM<c>FA are equivalent to LMDMA<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers) + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4]; address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] - 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

## F7.1.66 LDMDB/LDMEA

Load Multiple Decrement Before (Load Multiple Empty Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the lowest of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address.

Related system instructions are [LDM \(User registers\) on page F7-3044](#) and [LDM \(exception return\) on page F7-3042](#).

### Encoding T1 ARMv6T2, ARMv7

LDMDB<c> <Rn>{!}, <registers>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
1	1	1	0	1	0	0	1	0	0	W	1			Rn		P	M	(0)	register_list													

```
n = UInt(Rn); registers = P:M:'0':register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

LDMDB<c> <Rn>{!}, <registers>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		1	0	0	1	0	0	W	1			Rn	register_list																		

```
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDMDB/LDMEA on page AppxA-4707](#).

## Assembler syntax

LDMDB{<c>}{<q>} <Rn>{!}, <registers>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rn> The base register. The SP can be used.

! Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1.  
If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.

<registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2426](#).

Encoding T1 does not support a list containing only one register. If an LDMDB instruction with just one register <Rt> in the list is assembled to T32, it is assembled to the equivalent LDR{<c>}{<q>} <Rt>, [<Rn>, #-4]{!} instruction.

The SP can be in the list in A32 instructions, but not in T32 instructions. However, A32 instructions that include the SP in the list are deprecated.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#). In T32 instructions, if the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

A32 instructions that include both the LR and the PC in the list are deprecated.

LDMEA is a pseudo-instruction for LDMDB, referring to its use for popping data from Empty Ascending stacks.

The pre-UAL syntaxes LDM<c>DB and LDM<c>EA are equivalent to LDMDB<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n] - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4]; address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] - 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

### F7.1.67 LDMIB/LDMED

Load Multiple Increment Before (Load Multiple Empty Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address.

Related system instructions are [LDM \(User registers\) on page F7-3044](#) and [LDM \(exception return\) on page F7-3042](#).

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7  
 LDMIB<c> <Rn>{!}, <registers>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		1	0	0	1	1	0	W	1	Rn		register_list																			

```
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDMIB/LDMED on page AppxA-4706](#).

## Assembler syntax

LDMIB{<c>}{<q>} <Rn>{!}, <registers>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rn> The base register. The SP can be used.
- ! Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1.  
If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.
- <registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2426](#).  
The SP can be in the list. However, instructions that include the SP in the list are deprecated.  
The PC can be in the list. If it is, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).  
Instructions that include both the LR and the PC in the list are deprecated.

LDMED is a pseudo-instruction for LDMIB, referring to its use for popping data from Empty Descending stacks.

The pre-UAL syntaxes LDM<c>IB and LDM<c>ED are equivalent to LDMIB<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4]; address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

## F7.1.68 LDR (immediate, T32)

Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#) on page F2-2422.

**Encoding T1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

## Assembler syntax

LDR{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]	Offset: index==TRUE, wback==FALSE
LDR{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!	Pre-indexed: index==TRUE, wback==TRUE
LDR{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>	Post-indexed: index==FALSE, wback==TRUE

where:

<c>, <q>	See <i>Standard assembler syntax fields</i> on page F2-2415.
<Rt>	The destination register. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see <i>Pseudocode details of operations on the AArch32 general-purpose registers and the PC</i> on page E1-2296.
<Rn>	The base register. The SP can be used. For PC use see <i>LDR (literal)</i> on page F7-2638.
+/-	<p><b>+</b> or <b>omitted</b>      The immediate offset is to be added to the base register value (add == TRUE, encoded as U == 1 in encoding T4).</p> <p><b>-</b>                      The immediate offset is to be subtracted from the base register value. Encoding T4 must be used, with add == FALSE, encoded as U == 0.</p> <p>#0 and #-0 generate different instructions.</p>
<imm>	<p>The immediate offset used for forming the address. For the offset addressing syntax, &lt;imm&gt; can be omitted, meaning an offset of 0. Values are:</p> <p><b>Encoding T1</b> Multiples of 4 in the range 0-124.  <b>Encoding T2</b> Multiples of 4 in the range 0-1020.  <b>Encoding T3</b> Any value in the range 0-4095.  <b>Encoding T4</b> Any value in the range 0-255.</p>

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU[address,4];
    if wback then R[n] = offset_addr;
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data);
        else
            UNPREDICTABLE;
    else
        R[t] = data;
  
```

### F7.1.69 LDR (immediate, A32)

Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#) on page F2-2422.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

t = UInt(Rt); imm32 = ZeroExtend(imm12, 32); add = (U == '1');  
 if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

LDR<c> <Rt>, <label>

LDR<c> <Rt>, [PC, #-0] Special case

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	1	0	(1)	U	0	(0)	1	1	1	1	1	Rt			imm12														

t = UInt(Rt); imm32 = ZeroExtend(imm12, 32); add = (U == '1');

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDR \(literal\)](#) on page AppxA-4713.

## Assembler syntax

LDR{<c>}{<q>} <Rt>, <label> Normal form  
LDR{<c>}{<q>} <Rt>, [PC, #+/-<imm>] Alternative form

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rt> The destination register. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
- <label> The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are:
- Encoding T1** Multiples of four in the range 0 to 1020.
- Encoding T2 or A1** Any value in the range -4095 to 4095.
- If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1` in encoding T2.
- If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`. Negative offset is not available in encoding T1.

### Note

In examples in this manual, the syntax `=<value>` is used for the label of a memory word whose contents is constant and equal to `<value>`. The actual syntax for such a label is assembler-dependent.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2380](#).

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(15);
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,4];
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data);
        else
            UNPREDICTABLE;
    else
        R[t] = data;
```

### F7.1.71 LDR (register, T32)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses, see [Memory accesses](#) on page F2-2422.

The T32 form of LDR (register) does not support register writeback.

**Encoding T1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

LDR<c> <Rt>, [<Rn>, <Rm>]

 t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);  
 (shift\_t, shift\_n) = (SRTYPE\_LSL, UInt(imm2));  
 if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13  
 if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

**Modified operation in ThumbEE** ARM deprecates any use of ThumbEE instructions and they are not documented in this manual.

## Assembler syntax

LDR{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, <shift>}]    Offset addressing

where:

- <c>, <q>    See *Standard assembler syntax fields* on page F2-2415.
- <Rt>    The destination register. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2296.
- <Rn>    The base register. The SP can be used. In the T32 instruction set, the PC cannot be used with this form of the LDR instruction.
- +    In T32 instructions, the optionally shifted value of <Rm> is added to the base register value. T32 instructions cannot subtract <Rm> from the base register value.
- <Rm>    The offset that is optionally shifted and applied to the value of <Rn> to form the address.
- <shift>    The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. For encoding T2, <shift> can only be omitted, encoded as imm2 = 0b00, or LSL #<imm> with <imm> = 1, 2, or 3, and <imm> encoded in imm2.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = (R[n] + offset);

    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    R[t] = ZeroExtend(MemU[address,1], 32);
    if wback then R[n] = offset_addr;
```

## F7.1.75 LDRB (literal)

Load Register Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses on page F2-2422](#).

### Encoding T1 ARMv6T2, ARMv7

LDRB<c> <Rt>, <label>

LDRB<c> <Rt>, [PC, #-0] Special case

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	0	0	U	0	0	1	1	1	1	1	Rt	imm12														

```
if Rt == '1111' then SEE PLD;
t = UInt(Rt); imm32 = ZeroExtend(imm12, 32); add = (U == '1');
// ARMv8-A removes UNPREDICTABLE for R13
```

### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

LDRB<c> <Rt>, <label>

LDRB<c> <Rt>, [PC, #-0] Special case

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	1	0	(1)	U	1	(0)	1	1	1	1	1	Rt	imm12															

```
t = UInt(Rt); imm32 = ZeroExtend(imm12, 32); add = (U == '1');
if t == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDRB \(literal\) on page AppxA-4713](#).

## Assembler syntax

LDRB{<c>}{<q>} <Rt>, <label> Normal form  
LDRB{<c>}{<q>} <Rt>, [PC, #+/-<imm>] Alternative form

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rt> The destination register.

<label> The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2380](#).

The pre-UAL syntax `LDR<c>B` is equivalent to `LDRB<c>`.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(15);
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    R[t] = ZeroExtend(MemU[address,1], 32);
```

## F7.1.76 LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses see [Memory accesses on page F2-2422](#).

## Assembler syntax

LDRB{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>{, <shift>}]    Offset: index==TRUE, wback==FALSE  
LDRB{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>{, <shift>}]!    Pre-indexed: index==TRUE, wback==TRUE  
LDRB{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm>{, <shift>}    Post-indexed: index==FALSE, wback==TRUE

where:

<c>, <q>    See [Standard assembler syntax fields on page F2-2415](#).

<Rt>    The destination register.

<Rn>    The base register. The SP can be used. In the A32 instruction set the PC can be used, for the offset addressing form of the instruction only. In the T32 instruction set, the PC cannot be used with any of these forms of the LDRB instruction.

+/-    Is + or omitted if the optionally shifted value of <Rm> is to be added to the base register value (add == TRUE, encoded as U == 1 in encoding A1), or – if it is to be subtracted (permitted in A32 instructions only, add == FALSE, encoded as U == 0).

<Rm>    Contains the offset that is optionally shifted and applied to the value of <Rn> to form the address.

<shift>    The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. For encoding T2, <shift> can only be omitted, encoded as imm2 = 0b00, or LSL #<imm> with <imm> = 1, 2, or 3, and <imm> encoded in imm2. For encoding A1, see [Shifts applied to a register on page F2-2419](#).

The pre-UAL syntax LDR<c>B is equivalent to LDRB<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    R[t] = ZeroExtend(MemU[address,1],32);
    if wback then R[n] = offset_addr;
```

### F7.1.77 LDRBT

Load Register Byte Unprivileged loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses on page F2-2422](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

#### Encoding T1 ARMv6T2, ARMv7

LDRBT<c> <Rt>, [<Rn>, #<imm8>]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

register_form = TRUE; (shift_t, shift_n) = DecodeImmShift(type, imm5);
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDRBT on page AppxA-4709](#).

## Assembler syntax

LDRBT{<c>}{<q>} <Rt>, [<Rn> {, #<imm>}]	Offset: T32 only
LDRBT{<c>}{<q>} <Rt>, [<Rn>] {, #+/-<imm>}	Post-indexed: A32 only
LDRBT{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm> {, <shift>}	Post-indexed: A32 only

where:

<c>, <q>	See <a href="#">Standard assembler syntax fields on page F2-2415</a> .
<Rt>	The destination register.
<Rn>	The base register. The SP can be used.
+/-	Is + or omitted if <imm> or the optionally shifted value of <Rm> is to be added to the base register value (add == TRUE, encoded as U == 1 in encodings A1 and A2), or – if it is to be subtracted (permitted in A32 instructions only, add == FALSE, encoded as U == 0).
<imm>	The immediate offset applied to the value of <Rn>. Values are 0-255 for encoding T1, and 0-4095 for encoding A1. <imm> can be omitted, meaning an offset of 0.
<Rm>	Contains the offset that is optionally shifted and applied to the value of <Rn> to form the address.
<shift>	The shift to apply to the value read from <Rm>. If omitted, no shift is applied. <a href="#">Shifts applied to a register on page F2-2419</a> describes the shifts and how they are encoded.

The pre-UAL syntax LDR<c>BT is equivalent to LDRBT<c>.

## Operation

```

if ConditionPassed() then
    if CurrentModeIsHyp() then UNPREDICTABLE;           // Hyp mode
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = if register_form then Shift(R[m], shift_t, shift_n, APSR.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    R[t] = ZeroExtend(MemU_unpriv[address,1],32);
    if postindex then R[n] = offset_addr;
  
```

## F7.1.78 LDRD (immediate)

Load Register Dual (immediate) calculates an address from a base register value and an immediate offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#) on page F2-2422.

if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt); t2 = t+1; imm32 = ZeroExtend(imm4H:imm4L, 32); add = (U == '1');
if t2 == 15 then UNPREDICTABLE;
    
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDRD \(literal\)](#) on page AppxA-4717.

**Related encodings** See [Load/store dual, load/store exclusive, table branch](#) on page F3-2450.

## Assembler syntax

LDRD{<c>}{<q>} <Rt>, <Rt2>, <label> Normal form  
LDRD{<c>}{<q>} <Rt>, <Rt2>, [PC, #+/-<imm>] Alternative form

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).  
<Rt> The first destination register. For an A32 instruction, <Rt> must be even-numbered and not R14.  
<Rt2> The second destination register. For an A32 instruction, <Rt2> must be <R(t+1)>.  
<label> The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are:

**Encoding T1** Multiples of 4 in the range -1020 to 1020.

**Encoding A1** Any value in the range -255 to 255.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1.

If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2380](#).

The pre-UAL syntax LDR<c>D is equivalent to LDRD<c>.

## Operation

```
if ConditionPassed() then

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, +/-<Rm>]	Offset: index==TRUE, wback==FALSE
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, +/-<Rm>]!	Pre-indexed: index==TRUE, wback==TRUE
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], +/-<Rm>	Post-indexed: index==FALSE, wback==TRUE

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rt> The first destination register. This register must be even-numbered and not R14.

<Rt2> The second destination register. This register must be <R(t+1)>.

<Rn> The base register. The SP can be used. The PC can be used, for offset addressing only.

+/- Is + or omitted if the value of <Rm> is to be added to the base register value (add == TRUE, encoded as U == 1), or – if it is to be subtracted (add == FALSE, encoded as U == 0).

<Rm> Contains the offset that is applied to the value of <Rn> to form the address.

The pre-UAL syntax LDR<c>D is equivalent to LDRD<c>.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + R[m]) else (R[n] - R[m]);
    address = if index then offset_addr else R[n];
    if address == Align(address, 8) then
        data = MemA[address,8];
        if BigEndian() then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];

    if wback then R[n] = offset_addr;
  
```

## F7.1.81 LDREX

Load Register Exclusive calculates an address from a base register value and an immediate offset, loads a word from memory, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see [Synchronization and semaphores on page E2-2369](#). For information about memory accesses see [Memory accesses on page F2-2422](#).

### Encoding T1 ARMv6T2, ARMv7

```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDRH \(literal\)](#) on page AppxA-4714.

## Assembler syntax

LDRH{<c>}{<q>} <Rt>, <label> Normal form  
LDRH{<c>}{<q>} <Rt>, [PC, #+/-<imm>] Alternative form

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rt> The destination register.

<label> The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are:

**Encoding T1** Any value in the range -4095 to 4095.

**Encoding A1** Any value in the range -255 to 255.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2380](#).

The pre-UAL syntax `LDR<c>H` is equivalent to `LDRH<c>`.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(15);
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,2];
    R[t] = ZeroExtend(data, 32);
```

## F7.1.88 LDRH (register)

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses on page F2-2422](#).

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDRH \(register\) on page AppxA-4710](#).

**Modified operation in ThumbEE**

ARM deprecates any use of ThumbEE instructions and they are not documented in this manual.

## Assembler syntax

LDRH{<c>}{<q>} <Rt>, [<Rn>, <Rm>{, LSL #<imm>}]	Offset: index==TRUE, wback==FALSE
LDRH{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>]	Offset: index==TRUE, wback==FALSE
LDRH{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>!]	Pre-indexed: index==TRUE, wback==TRUE
LDRH{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm>	Post-indexed: index==FALSE, wback==TRUE

where:

<c>, <q>	See <a href="#">Standard assembler syntax fields on page F2-2415</a> .
<Rt>	The destination register.
<Rn>	The base register. The SP can be used. In the A32 instruction set the PC can be used, for offset addressing forms of the instruction only. In the T32 instruction set, the PC cannot be used for any of these forms of the LDRH instruction.
+/-	Is + or omitted if the optionally shifted value of <Rm> is to be added to the base register value (add == TRUE), or – if it is to be subtracted (permitted in A32 instructions only, add == FALSE).
<Rm>	Contains the offset that is optionally left shifted and added to the value of <Rn> to form the address.
<imm>	If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. Only encoding T2 is permitted, and <imm> is encoded in imm2.  If absent, no shift is specified and all encodings are permitted. In encoding T2, imm2 is encoded as 0b00.

The pre-UAL syntax LDR<c>H is equivalent to LDRH<c>.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    data = MemU[address,2];
    if wback then R[n] = offset_addr;
    R[t] = ZeroExtend(data, 32);
  
```

## F7.1.89 LDRHT

Load Register Halfword Unprivileged loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses on page F2-2422](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

## Assembler syntax

LDRSB{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]	Offset: index==TRUE, wback==FALSE
LDRSB{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!	Pre-indexed: index==TRUE, wback==TRUE
LDRSB{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>	Post-indexed: index==FALSE, wback==TRUE

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rt> The destination register.

<Rn> The base register. The SP can be used. For PC use see [LDRSB \(literal\) on page F7-2676](#).

+/- Is + or omitted to indicate that the immediate offset is added to the base register value (add == TRUE), or – to indicate that the offset is to be subtracted (add == FALSE). Different instructions are generated for #0 and #-0.

<imm> The immediate offset used for forming the address. For the offset addressing syntax, <imm> can be omitted, meaning an offset of 0. Values are:

**Encoding T1** Any value in the range 0-4095.

**Encoding T2 or A1** Any value in the range 0-255.

The pre-UAL syntax LDR<c>SB is equivalent to LDRSB<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    R[t] = SignExtend(MemU[address,1], 32);
    if wback then R[n] = offset_addr;
```

### F7.1.91 LDRSB (literal)

Load Register Signed Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#) on page F2-2422.

#### Encoding T1 ARMv6T2, ARMv7

```
t = UInt(Rt); imm32 = ZeroExtend(imm4H:imm4L, 32); add = (U == '1');
if t == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDRSB \(literal\)](#) on page AppxA-4714.

## Assembler syntax

LDRSB{<c>}{<q>} <Rt>, <label> Normal form  
LDRSB{<c>}{<q>} <Rt>, [PC, #+/-<imm>] Alternative form

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rt> The destination register.

<label> The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are:

**Encoding T1** Any value in the range -4095 to 4095.

**Encoding A1** Any value in the range -255 to 255.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2380](#).

The pre-UAL syntax `LDR<c>SB` is equivalent to `LDRSB<c>`.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(15);
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    R[t] = SignExtend(MemU[address,1], 32);
```

## F7.1.92 LDRSB (register)

Load Register Signed Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses on page F2-2422](#).

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDRSBT on page AppxA-4711](#).

## Assembler syntax

LDRSBT{<c>}{<q>} <Rt>, [<Rn> {, #<imm>}]	Offset: T32 only
LDRSBT{<c>}{<q>} <Rt>, [<Rn>] {, #+/-<imm>}	Post-indexed: A32 only
LDRSBT{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm>	Post-indexed: A32 only

where:

<c>, <q>	See <a href="#">Standard assembler syntax fields on page F2-2415</a> .
<Rt>	The destination register.
<Rn>	The base register. The SP can be used.
+/-	Is + or omitted if <imm> or the optionally shifted value of <Rm> is to be added to the base register value (add == TRUE), or – if it is to be subtracted (permitted in A32 instructions only, add == FALSE).
<imm>	The immediate offset applied to the value of <Rn>. Any value in the range 0-255 is permitted. <imm> can be omitted, meaning an offset of 0.
<Rm>	Contains the offset that is applied to the value of <Rn> to form the address.

## Operation

```
if ConditionPassed() then
    if CurrentModeIsHyp() then UNPREDICTABLE;           // Hyp mode
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    R[t] = SignExtend(MemU_unpriv[address,1], 32);
    if postindex then R[n] = offset_addr;
```

## F7.1.94 LDRSH (immediate)

Load Register Signed Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses on page F2-2422](#).

## Assembler syntax

LDRSH{<c>}{<q>} <Rt>, <label> Normal form  
LDRSH{<c>}{<q>} <Rt>, [PC, #+/-<imm>] Alternative form

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rt> The destination register.

<label> The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are:

**Encoding T1** Any value in the range -4095 to 4095.

**Encoding A1** Any value in the range -255 to 255.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2380](#).

The pre-UAL syntax `LDR<c>SH` is equivalent to `LDRSH<c>`.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(15);
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,2];
    R[t] = SignExtend(data, 32);
```

## F7.1.96 LDRSH (register)

Load Register Signed Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses on page F2-2422](#).

### Modified operation in ThumbEE

ARM deprecates any use of ThumbEE instructions and they are not documented in this manual.

## Assembler syntax

LDRSH{<c>}{<q>} <Rt>, [<Rn>, <Rm>{, LSL #<imm>}]	Offset: index==TRUE, wback==FALSE
LDRSH{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>]	Offset: index==TRUE, wback==FALSE
LDRSH{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>!]	Pre-indexed: index==TRUE, wback==TRUE
LDRSH{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm>	Post-indexed: index==FALSE, wback==TRUE

where:

<c>, <q>	See <a href="#">Standard assembler syntax fields on page F2-2415</a> .
<Rt>	The destination register.
<Rn>	The base register. The SP can be used. In the A32 instruction set the PC can be used, for the offset addressing forms of the instruction only. In the T32 instruction set, the PC cannot be used for any of these forms of the LDRSH instruction.
+/-	Is + or omitted if the optionally shifted value of <Rm> is to be added to the base register value (add == TRUE), or – if it is to be subtracted (permitted in A32 instructions only, add == FALSE).
<Rm>	Contains the offset that is optionally left shifted and added to the value of <Rn> to form the address.
<imm>	If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. Only encoding T2 is permitted, and <imm> is encoded in imm2. If absent, no shift is specified and all encodings are permitted. In encoding T2, imm2 is encoded as 0b00.

The pre-UAL syntax LDR<c>SH is equivalent to LDRSH<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    data = MemU[address,2];
    if wback then R[n] = offset_addr;
    R[t] = SignExtend(data, 32);
```

## F7.1.97 LDRSHT

Load Register Signed Halfword Unprivileged loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#) on page F2-2422.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRSHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

### Encoding T1 ARMv6T2, ARMv7

    R[t] = SignExtend(data, 32);
```

## F7.1.98 LDRT

Load Register Unprivileged loads a word from memory, and writes it to a register. For information about memory accesses see [Memory accesses on page F2-2422](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

LSL{S}{<c>}{<q>} {<Rd>}, <Rm>, #<imm5>

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>     See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>        The destination register.  
In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
- <Rm>        The first operand register. The PC can be used in A32 instructions.
- <imm5>      The shift amount, in the range 1 to 31. See [Shifts applied to a register on page F2-2419](#).

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry) = Shift_C(R[m], SRTYPE_LSL, shift_n, APSR.C);
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

## F7.1.100 LSL (register)

Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register. It can optionally update the condition flags based on the result.

**Encoding T1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

        APSR.C = carry;
        // APSR.V unchanged
```

### F7.1.103 MCR, MCR2

Move to Coprocessor from general-purpose register passes the value of a general-purpose register to a coprocessor. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1`, `opc2`, `CRn`, and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid MCR and MCR2 instructions when `coproc` is in the range p8-p15. For more information see [Coprocessor support on page E1-2331](#).

In an implementation that includes EL2, MCR accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an MCR instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [AArch32 control of traps to the hypervisor on page G1-3503](#).

———— **Note** —————

Because of the range of possible traps to Hyp mode, the MCR pseudocode does not show these possible traps.

**Encoding T1/A1**      ARMv6T2, ARMv7 for encoding T1

if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

**Advanced SIMD and floating-point**      See [8, 16, and 32-bit transfer between general-purpose and extension registers on page F5-2518](#)

## Assembler syntax

MCR{2}{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

where:

- 2 If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 MCR2 instruction must be unconditional.
- <coproc> The name of the coprocessor. The generic coprocessor names are p0-p15.
- <opc1> Is a coprocessor-specific opcode in the range 0 to 7.
- <Rt> Is the general-purpose register whose value is transferred to the coprocessor.
- <CRn> Is the destination coprocessor register.
- <CRm> Is an additional destination coprocessor register.
- <opc2> Is a coprocessor-specific opcode in the range 0-7. If omitted, <opc2> is assumed to be 0.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Cproc_Accepted(cp, ThisInstr()) then
        GenerateCoproprocessorException();
    else
        Cproc_SendOneWord(R[t], cp, ThisInstr());
```

## F7.1.104 MCRR, MCRR2

Move to Coprocessor from two general-purpose registers passes the values of two general-purpose registers to a coprocessor. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1` and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid MCRR and MCRR2 instructions when `coproc` is in the range p8-p15. For more information see [Coprocessor support on page E1-2331](#).

In an implementation that includes EL2, MCRR accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an MCRR instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [AArch32 control of traps to the hypervisor on page G1-3503](#).

### ———— Note ————

Because of the range of possible traps to Hyp mode, the MCRR pseudocode does not show these possible traps.

## Assembler syntax

MCRR{2}{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

where:

- 2                    If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
- <c>, <q>            See [Standard assembler syntax fields on page F2-2415](#). An A32 MCRR2 instruction must be unconditional.
- <coproc>           The name of the coprocessor.  
                    The generic coprocessor names are p0-p15.
- <opc1>             Is a coprocessor-specific opcode in the range 0 to 15.
- <Rt>                Is the first general-purpose register whose value is transferred to the coprocessor.
- <Rt2>              Is the second general-purpose register whose value is transferred to the coprocessor.
- <CRm>              Is the destination coprocessor register.

---

### Note

---

The relative significance of Rt2 and Rt is IMPLEMENTATION DEFINED, but all uses within this manual treat Rt2 as more significant than Rt

---

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Cproc_Accepted(cp, ThisInstr()) then
        GenerateCoproprocessorException();
    else
        Cproc_SendTwoWords(R[t2], R[t], cp, ThisInstr());
```

## F7.1.105 MLA

Multiply Accumulate multiplies two register values, and adds a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

In an A32 instruction, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

### Encoding T1 ARMv6T2, ARMv7

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); a = UInt(Ra); setflags = (S == '1');
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

MLA{S}{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

where:

S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.  
S can be specified only for the A32 instruction set.

<c>, <q>     See *Standard assembler syntax fields* on page F2-2415.

<Rd>        The destination register.

<Rn>        The first operand register.

<Rm>        The second operand register.

<Ra>        The register containing the accumulate value.

The pre-UAL syntax MLA<c>S is equivalent to MLAS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]); // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]); // operand2 = UInt(R[m]) produces the same final results
    addend = SInt(R[a]); // addend = UInt(R[a]) produces the same final results
    result = operand1 * operand2 + addend;
    R[d] = result<31:0>;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result<31:0>);
        // APSR.C, APSR.V unchanged
```

## F7.1.106 MLS

Multiply and Subtract multiplies two register values, and subtracts the product from a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

### Encoding T1 ARMv6T2, ARMv7

d = UInt(Rd); setflags = FALSE; imm32 = ZeroExtend(imm4:imm12, 32);  
 if d == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

MOV{S}{<c>}{<q>} <Rd>, #<const>                      All encodings permitted  
MOVW{<c>}{<q>} <Rd>, #<const>                      Only encoding T3 or A2 permitted

where:

- S                      If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>                See *Standard assembler syntax fields* on page F2-2415.
- <Rd>                    The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions (T32)* on page F7-3066 or *SUBS PC, LR and related instructions (A32)* on page F7-3068.
- In A32 instructions, if S is not specified and <Rd> is the PC, encoding A2 is not permitted, and for encoding A1 the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2296.
- <const>                The immediate value to be placed in <Rd>. The range of values is 0-255 for encoding T1 and 0-65535 for encoding T3 or A2. See *Modified immediate constants in T32 instructions* on page F3-2444 or *Modified immediate constants in A32 instructions* on page F4-2472 for the range of values for encoding T2 or A1.
- When both 32-bit encodings are available for an instruction, encoding T2 or A1 is preferred to encoding T3 or A2 (if encoding T3 or A2 is required, use the MOVW syntax).

The pre-UAL syntax MOV<c>S is equivalent to MOV{S}<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = imm32;
    if d == 15 then                      // Can only occur for encoding A1
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

### F7.1.108 MOV (register, T32)

Move (register) copies a value from a register to the destination register. It can optionally update the condition flags based on the value.

**Encoding T1** ARMv6\*, ARMv7 if <Rd> and <Rm> both from R0-R7  
 ARMv4T, ARMv5T\*, ARMv6\*, ARMv7 otherwise  
 MOV<c> <Rd>, <Rm> If <Rd> is the PC, must be outside or last in IT block.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	1	1	0	D			Rm				Rd

d = UInt(D:Rd); m = UInt(Rm); setflags = FALSE;  
 if d == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;

**Encoding T2** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7  
 MOVS <Rd>, <Rm> Not permitted in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0		Rm				Rd

d = UInt(Rd); m = UInt(Rm); setflags = TRUE;  
 if InITBlock() then UNPREDICTABLE;

**Encoding T3** ARMv6T2, ARMv7  
 MOV{S}<c>.W <Rd>, <Rm>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	1	0	0	1	0	S	1	1	1	1	(0)	0	0	0		Rd	0	0	0	0		Rm				

d = UInt(Rd); m = UInt(Rm); setflags = (S == '1');  
 if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [MOV \(register, T32\)](#) on page AppxA-4719.

## Assembler syntax

MOV{S}{<c>}{<q>} <Rd>, <Rm>

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>      See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>        The destination register. This register can be the SP or PC. S must not be specified if <Rd> is the SP. If <Rd> is the PC and S is not specified:
- The instruction causes a branch to the address moved to the PC. This is a simple branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
  - The instruction must either be outside an IT block or the last instruction of an IT block.
- <Rm>        The source register. This register can be the SP or PC. S must not be specified if <Rm> is the SP or PC.

Encoding T3 is not permitted if <Rd> or <Rm> is the PC.

### Note

- ARM deprecates the use of the following MOV (register) instructions:
  - Ones in which <Rd> is the SP or PC and <Rm> is also the SP or PC.
  - Ones in which S is specified and <Rm> is the SP, or <Rm> is the PC.
- See also [Branch instructions on page F1-2382](#) about the use of the MOV PC, LR instruction.

The pre-UAL syntax MOV<c>S is equivalent to MOV{S}<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[m];
    if d == 15 then
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            // APSR.C unchanged
            // APSR.V unchanged
```

## F7.1.109 MOV (register, A32)

Move (register) copies a value from a register to the destination register. It can optionally update the condition flags based on the value.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

MOV{S}<c> <Rd>, <Rm>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	0	1	1	0	1	S	(0)	(0)	(0)	(0)	Rd				0	0	0	0	0	0	0	0	Rm				

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;  
 d = UInt(Rd); m = UInt(Rm); setFlags = (S == '1');

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

MOV{S}{<c>}{<q>} <Rd>, <Rm>

where:

- S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register. If S is specified and <Rd> is the PC, see [SUBS PC, LR and related instructions \(A32\) on page F7-3068](#). This register can be the SP or PC.  
 If <Rd> is the PC and S is not specified, the instruction causes a branch to the address moved to the PC. This is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
- <Rm> The source register. This register can be the SP or PC.

### Note

- ARM deprecates the use of the following MOV (register) instructions:
  - Ones in which <Rd> is the SP or PC and <Rm> is also the SP or PC.
  - Ones in which S is specified and <Rd> is the SP, <Rm> is the SP, or <Rm> is the PC.
- See also [Branch instructions on page F1-2382](#) about the use of the MOV PC, LR instruction.

The pre-UAL syntax MOV<c>S is equivalent to MOV{S}<c>.

### Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[m];
    if d == 15 then
        ALUWritePC(result); // setFlags is always FALSE here
    else
        R[d] = result;
        if setFlags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            // APSR.C unchanged
            // APSR.V unchanged
  
```

## F7.1.110 MOV (shifted register)

For the special case of MOV<sub>S</sub> where <Rd> is the PC, see *SUBS PC, LR and related instructions (T32)* on page F7-3066 and *SUBS PC, LR and related instructions (A32)* on page F7-3068. Otherwise, MOV (shifted register) is a pseudo-instruction for ASR, LSL, LSR, ROR, and RRX. For more information see the following sections:

- *ASR (immediate)* on page F7-2562.
- *ASR (register)* on page F7-2564.
- *LSL (immediate)* on page F7-2692.
- *LSL (register)* on page F7-2694.
- *LSR (immediate)* on page F7-2696.
- *LSR (register)* on page F7-2698.
- *ROR (immediate)* on page F7-2776.
- *ROR (register)* on page F7-2778.
- *RRX* on page F7-2780.

### Assembler syntax

Table F7-2 shows the equivalences between MOV (shifted register) and other instructions.

**Table F7-2 MOV (shifted register) equivalences**

MOV instruction	Canonical form
MOV{S} <Rd>, <Rm>, ASR #<n>	ASR{S} <Rd>, <Rm>, #<n>
MOV{S} <Rd>, <Rm>, LSL #<n>	LSL{S} <Rd>, <Rm>, #<n>
MOV{S} <Rd>, <Rm>, LSR #<n>	LSR{S} <Rd>, <Rm>, #<n>
MOV{S} <Rd>, <Rm>, ROR #<n>	ROR{S} <Rd>, <Rm>, #<n>
MOV{S} <Rd>, <Rm>, ASR <Rs>	ASR{S} <Rd>, <Rm>, <Rs>
MOV{S} <Rd>, <Rm>, LSL <Rs>	LSL{S} <Rd>, <Rm>, <Rs>
MOV{S} <Rd>, <Rm>, LSR <Rs>	LSR{S} <Rd>, <Rm>, <Rs>
MOV{S} <Rd>, <Rm>, ROR <Rs>	ROR{S} <Rd>, <Rm>, <Rs>
MOV{S} <Rd>, <Rm>, RRX	RRX{S} <Rd>, <Rm>

Disassembly produces the canonical form of the instruction.

## F7.1.111 MOV<sub>T</sub>

Move Top writes an immediate value to the top halfword of the destination register. It does not affect the contents of the bottom halfword.

### Encoding T1 ARMv6T2, ARMv7

MOV<sub>T</sub><c> <Rd>, #<imm16>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

d = UInt(Rd); imm16 = imm4:imm12;  
 if d == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

MOVT{<c>}{<q>} <Rd>, #<imm16>

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2415.

<Rd> The destination register.

<imm16> The immediate value to be written to <Rd>. It must be in the range 0-65535.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R[d]<31:16> = imm16;
    // R[d]<15:0> unchanged
```

## F7.1.112 MRC, MRC2

Move to general-purpose register from Coprocessor causes a coprocessor to transfer a value to a general-purpose register or to the condition flags. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1`, `opc2`, `CRn`, and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid MRC and MRC2 instructions when `coproc` is in the range p8-p15. For more information see [Coprocesor support on page E1-2331](#).

In an implementation that includes EL2, MRC accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an MRC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [AArch32 control of traps to the hypervisor on page G1-3503](#).

### ———— Note —————

Because of the range of possible traps to Hyp mode, the MRC pseudocode does not show these possible traps.

**Encoding T1/A1** ARMv6T2, ARMv7 for encoding T1  
 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7 for encoding A1

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

**Advanced SIMD and floating-point** See [8, 16, and 32-bit transfer between general-purpose and extension registers on page F5-2518](#)

## Assembler syntax

MRC{2}{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

where:

- 2            If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
- <c>, <q>     See [Standard assembler syntax fields on page F2-2415](#). An A32 MRC2 instruction must be unconditional.
- <coproc>    The name of the coprocessor. The generic coprocessor names are p0-p15.
- <opc1>      Is a coprocessor-specific opcode in the range 0 to 7.
- <Rt>        Is the destination general-purpose register. This register can be R0-R14 or APSR\_nzcv. The last form writes bits[31:28] of the transferred value to the N, Z, C and V condition flags and is specified by setting the Rt field of the encoding to 0b1111. In pre-UAL assembler syntax, PC was written instead of APSR\_nzcv to select this form.
- <CRn>      Is the coprocessor register that contains the first operand.
- <CRm>      Is an additional source or destination coprocessor register.
- <opc2>      Is a coprocessor-specific opcode in the range 0 to 7. If omitted, <opc2> is assumed to be 0.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coprocc_Accepted(cp, ThisInstr()) then
        GenerateCoproccorException();
    else
        value = Coproc_GetOneWord(cp, ThisInstr());
        if t != 15 then
            R[t] = value;
        else
            APSR.N = value<31>;
            APSR.Z = value<30>;
            APSR.C = value<29>;
            APSR.V = value<28>;
            // value<27:0> are not used.
```

### F7.1.113 MRRC, MRRC2

Move to two general-purpose registers from Coprocessor causes a coprocessor to transfer values to two general-purpose registers. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1` and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid MRRC and MRRC2 instructions when coproc is in the range p8-p15. For more information see [Coprocessor support on page E1-2331](#).

In an implementation that includes EL2, MRRC accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an MRRC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [AArch32 control of traps to the hypervisor on page G1-3503](#).

———— **Note** —————

Because of the range of possible traps to Hyp mode, the MRRC pseudocode does not show these possible traps.

**Encoding T1/A1** ARMv6T2, ARMv7 for encoding T1  
 ARMv5TE\*, ARMv6\*, ARMv7 for encoding A1

 if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE;  
 // ARMv8-A removes UNPREDICTABLE for R13

**Advanced SIMD and floating-point** See [64-bit transfers between general-purpose and extension registers on page F5-2519](#)

## Assembler syntax

MRRC{2}{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

where:

- 2                    If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
- <c>, <q>            See [Standard assembler syntax fields on page F2-2415](#). An A32 MRRC2 instruction must be unconditional.
- <coproc>           The name of the coprocessor. The generic coprocessor names are p0-p15.
- <opc1>             Is a coprocessor-specific opcode in the range 0 to 15.
- <Rt>                Is the first destination general-purpose register.
- <Rt2>              Is the second destination general-purpose register.
- <CRm>              Is the coprocessor register that supplies the data to be transferred.

---

### Note

---

The relative significance of Rt2 and Rt is IMPLEMENTATION DEFINED, but all uses within this manual treat Rt2 as more significant than Rt

---

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Cproc_Accepted(cp, ThisInstr()) then
        GenerateCoproprocessorException();
    else
        (R[t2], R[t]) = Cproc_GetTwoWords(cp, ThisInstr());
```

## F7.1.114 MRS

Move to Register from Special register moves the value from the APSR into a general-purpose register.

For details of system level use of this instruction, see [MRS on page F7-3046](#).

### Encoding T1 ARMv6T2, ARMv7

MRS<c> <Rd>, <spec\_reg>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	1	1	0	(1)	(1)	(1)	(1)	1	0	(0)	0	Rd	(0)	(0)	0	(0)	(0)	(0)	(0)	(0)			

d = UInt(Rd);

if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

MRS<c> <Rd>, <spec\_reg>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond	0	0	0	1	0	0	0	0	(1)	(1)	(1)	(1)	Rd	(0)	(0)	0	(0)	0	0	0	0	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	

d = UInt(Rd);

if d == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

MRS{<c>}{<q>} <Rd>, <spec\_reg>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<spec\_reg> Is one of:

- APSR.
- CPSR.

When the MRS instruction is executed in User mode, CPSR is treated as a synonym of APSR.

ARM recommends that application level software uses the APSR form. For more information, see [The Application Program Status Register \(APSR\) on page E1-2297](#).

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R[d] = APSR;
```

### F7.1.115 MRS (Banked register)

Move to Register from Banked or Special register is a system instruction, see [MRS \(Banked register\)](#) on page F7-3048.

### F7.1.116 MSR (immediate)

Move immediate value to Special register moves selected bits of an immediate value to the corresponding bits in the APSR.

For details of system level use of this instruction, see [MSR \(immediate\)](#) on page F7-3052.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

MSR<c> <spec\_reg>, #<const>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	1	1	0	0	1	0	mask	0	0	(1)	(1)	(1)	(1)	imm12														

if mask == '00' then SEE "Related encodings";  
 imm32 = ARMEExpandImm(imm12); write\_nzcvq = (mask<1> == '1'); write\_g = (mask<0> == '1');

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

**Related encodings** See [MSR \(immediate\)](#), and [hints](#) on page F4-2478.

## Assembler syntax

MSR{<c>}{<q>} <spec\_reg>, #<imm>

where:

<c>, <q>	See <a href="#">Standard assembler syntax fields</a> on page F2-2415.
<spec_reg>	Is one of: <ul style="list-style-type: none"><li>• APSR_&lt;bits&gt;.</li><li>• CPSR_&lt;fields&gt;.</li></ul> ARM recommends that application level software uses the APSR forms. For more information, see <a href="#">The Application Program Status Register (APSR)</a> on page E1-2297.
<imm>	Is the immediate value to be transferred to <spec_reg>. See <a href="#">Modified immediate constants in A32 instructions</a> on page F4-2472 for the range of values.
<bits>	Is one of nzcvcq, g, or nzcvcqg. In the A and R profiles: <ul style="list-style-type: none"><li>• APSR_nzcvcq is the same as CPSR_f.</li><li>• APSR_g is the same as CPSR_s.</li><li>• APSR_nzcvcqg is the same as CPSR_fs.</li></ul>
<fields>	Is a sequence of one or more of the following: s, f.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_nzcvcq then
        APSR.N = imm32<31>;
        APSR.Z = imm32<30>;
        APSR.C = imm32<29>;
        APSR.V = imm32<28>;
        APSR.Q = imm32<27>;
    if write_g then
        APSR.GE = imm32<19:16>;
```

## Usage

For details of the APSR see [The Application Program Status Register \(APSR\)](#) on page E1-2297. Because of the Do-Not-Modify nature of its reserved bits, the immediate form of MSR is normally only useful at the Application level for writing to APSR\_nzcvcq (CPSR\_f).

For the A and R profiles, [MSR \(immediate\)](#) on page F7-3052 describes additional functionality that is available using the reserved bits. This includes some deprecated functionality that is also available to unprivileged software and therefore can be used at the Application level.

### F7.1.117 MSR (register)

Move to Special register from general-purpose register moves selected bits of a general-purpose register to the APSR.

For details of system level use of this instruction, see [MSR \(register\) on page F7-3054](#).

#### Encoding T1 ARMv6T2, ARMv7

MSR<c> <spec\_reg>, <Rn>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	0	0	Rn				1	0	(0)	0	mask	0	0	(0)	(0)	0	(0)	(0)	(0)	(0)	(0)	

n = UInt(Rn); write\_nzcvq = (mask<1> == '1'); write\_g = (mask<0> == '1');  
 if mask == '00' then UNPREDICTABLE;  
 if n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

#### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

MSR<c> <spec\_reg>, <Rn>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	0	1	0	0	1	0	mask	0	0	(1)	(1)	(1)	(1)	(0)	(0)	0	(0)	0	0	0	0	0	0	0	0	Rn		

n = UInt(Rn); write\_nzcvq = (mask<1> == '1'); write\_g = (mask<0> == '1');  
 if mask == '00' then UNPREDICTABLE;  
 if n == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [MSR \(register\) on page AppxA-4720](#).

## Assembler syntax

MSR{<c>}{<q>} <spec\_reg>, <Rn>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<spec\_reg> Is one of:

- APSR\_<bits>.
- CPSR\_<fields>.

ARM recommends that application level software uses the APSR form. For more information, see [The Application Program Status Register \(APSR\) on page E1-2297](#).

<Rn> Is the general-purpose register to be transferred to <spec\_reg>.

<bits> Is one of nzcvcq, g, or nzcvcqg.

In the A and R profiles:

- APSR\_nzcvcq is the same as CPSR\_f.
- APSR\_g is the same as CPSR\_s.
- APSR\_nzcvcqg is the same as CPSR\_fs.

<fields> Is a sequence of one or more of the following: s, f.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_nzcvcq then
        APSR.N = R[n]<31>;
        APSR.Z = R[n]<30>;
        APSR.C = R[n]<29>;
        APSR.V = R[n]<28>;
        APSR.Q = R[n]<27>;
    if write_g then
        APSR.GE = R[n]<19:16>;
```

## Usage

For details of the APSR see [The Application Program Status Register \(APSR\) on page E1-2297](#). Because of the Do-Not-Modify nature of its reserved bits, a read-modify-write sequence is normally needed when the MSR instruction is being used at Application level and its destination is not APSR\_nzcvcq (CPSR\_f).

For the A and R profiles, [MSR \(register\) on page F7-3054](#) describes additional functionality that is available using the reserved bits. This includes some deprecated functionality that is also available to unprivileged software and therefore can be used at the Application level.

### F7.1.118 MSR (Banked register)

Move to Banked or Special register from general-purpose register is a system instruction, see [MSR \(Banked register\)](#) on page F7-3050.

### F7.1.119 MUL

Multiply multiplies two register values. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

Optionally, it can update the condition flags based on the result. In the T32 instruction set, this option is limited to only a few forms of the instruction. Use of this option adversely affects performance on many implementations.

#### Encoding T1 ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

MULS <Rdm>, <Rn>, <Rdm> Outside IT block.

MUL<C> <Rdm>, <Rn>, <Rdm> Inside IT block.

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = FALSE;  
 if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

#### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

MUL{S}<C> <Rd>, <Rn>, <Rm>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	0	0	0	0	0	0	S	Rd			(0)	(0)	(0)	(0)	Rm			1	0	0	1	Rn						

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');  
 if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

MUL{S}{<c>}{<q>} <Rd>, <Rn>{, <Rm>}

where:

S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.  
              In the T32 instruction set, S can be specified only if both <Rn> and <Rm> are R0-R7 and the instruction is outside an IT block.

<c>, <q>      See [Standard assembler syntax fields on page F2-2415](#).

<Rd>          The destination register.

<Rn>          The first operand register.

<Rm>          The second operand register. If omitted, <Rd> is used.

The pre-UAL syntax MUL<c>S is equivalent to MULS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]); // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]); // operand2 = UInt(R[m]) produces the same final results
    result = operand1 * operand2;
    R[d] = result<31:0>;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result<31:0>);
        // APSR.C, APSR.V unchanged
```

### F7.1.120 MVN (immediate)

Bitwise NOT (immediate) writes the bitwise inverse of an immediate value to the destination register. It can optionally update the condition flags based on the value.

#### Encoding T1 ARMv6T2, ARMv7

MVN{S}<c> <Rd>, #<const>

## Assembler syntax

MVN{S}{<c>}{<q>} <Rd>, <Rm> {, <shift>}

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>     See *Standard assembler syntax fields* on page F2-2415.
- <Rd>        The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions (T32)* on page F7-3066 or *SUBS PC, LR and related instructions (A32)* on page F7-3068.  
In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2296.
- <Rm>        The register that is optionally shifted and used as the source register. The PC can be used in A32 instructions.
- <shift>     The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page F2-2419 describes the shifts and how they are encoded.

The pre-UAL syntax MVN<c>S is equivalent to MVNS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = NOT(shifted);
    if d == 15 then           // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

### F7.1.122 MVN (register-shifted register)

Bitwise NOT (register-shifted register) writes the bitwise inverse of a register-shifted register value to the destination register. It can optionally update the condition flags based on the result.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7  
 MVN{S}<c> <Rd>, <Rm>, <type> <Rs>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	0	1	1	1	1	S	(0)	(0)	(0)	(0)	Rd				Rs		0	type	1	Rm								

```
d = UInt(Rd); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

#### Assembler syntax

MVN{S}{<c>}{<q>} <Rd>, <Rm>, <type> <Rs>

where:

- S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register.
- <Rm> The register that is shifted and used as the operand.
- <type> The type of shift to apply to the value read from <Rm>. It must be one of:
  - ASR Arithmetic shift right, encoded as type = 0b10.
  - LSL Logical shift left, encoded as type = 0b00.
  - LSR Logical shift right, encoded as type = 0b01.
  - ROR Rotate right, encoded as type = 0b11.
- <Rs> The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax MVN<c>S is equivalent to MVNS<c>.

#### Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  shift_n = UInt(R[s]<7:0>);
  (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
  result = NOT(shifted);
  R[d] = result;
  if setflags then
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    // APSR.V unchanged
```

## F7.1.123 NEG

Negate is a pre-UAL synonym for RSB (immediate) with an immediate value of 0. For details see [RSB \(immediate\)](#) on page F7-2782.

### Assembler syntax

NEG{<c>}{<q>} <Rd>, <Rm>

This is equivalent to:

RSBS{<c>}{<q>} <Rd>, <Rm>, #0

## F7.1.124 NOP

No Operation does nothing. This instruction can be used for instruction alignment purposes.

—— **Note** ——

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.

### Encoding T1 ARMv6T2, ARMv7

NOP<c>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	1	1	1	0	0	0	0	0	0	0	0

// No additional decoding required

### Encoding T2 ARMv6T2, ARMv7

NOP<c>.W

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

// No additional decoding required

### Encoding A1 ARMv6K, ARMv6T2, ARMv7

NOP<c>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond	0	0	1	1	0	0	1	0	0	0	0	0	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	0	0	0	0	0	0	0	0	0	0

// No additional decoding required

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

NOP{<c>}{<q>}

where:

{<c>}{<q>} See [Standard assembler syntax fields on page F2-2415](#).

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
// Do nothing
```

## F7.1.125 ORN (immediate)

Bitwise OR NOT (immediate) performs a bitwise (inclusive) OR of a register value and the complement of an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding T1** ARMv6T2, ARMv7

ORN{S}<c> <Rd>, <Rn>, #<const>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	i	0	0	0	1	1	S		Rn		0	imm3		Rd									imm8				

```

if Rn == '1111' then SEE MVN (immediate);
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1');
(imm32, carry) = ThumbExpandImm_C(i:imm3:imm8, APSR.C);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
  
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

ORN{S}{<c>}{<q>} {<Rd>}, <Rn>, #<const>

where:

- S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register.
- <Rn> The register that contains the operand.
- <const> The immediate value to be bitwise inverted and ORed with the value obtained from <Rn>. See [Modified immediate constants in T32 instructions on page F3-2444](#) for the range of values.

### Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] OR NOT(imm32);
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        // APSR.V unchanged
  
```

### F7.1.126 ORN (register)

Bitwise OR NOT (register) performs a bitwise (inclusive) OR of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding T1** ARMv6T2, ARMv7

ORN{S}<C> <Rd>, <Rn>, <Rm>{, <shift>}

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	1	0	0	1	1	S	Rn				(0)	imm3			Rd			imm2		type	Rm					

```

if Rn == '1111' then SEE MVN (register);
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
    
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

ORN{S}{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift>}

where:

- S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register.
- <Rn> The first operand register.
- <Rm> The register that is optionally shifted and used as the second operand.
- <shift> The shift to apply to the value read from <Rm>. If omitted, no shift is applied. [Shifts applied to a register on page F2-2419](#) describes the shifts and how they are encoded.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] OR NOT(shifted);
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        // APSR.V unchanged
```

### F7.1.127 ORR (immediate)

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

#### Encoding T1 ARMv6T2, ARMv7

ORR{S}<c> <Rd>, <Rn>, #<const>

(imm32, carry) = ThumbExpandImm_C(i:imm3:imm8, APSR.C);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
    
```

#### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

ORR{S}<c> <Rd>, <Rn>, #<const>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	1	1	1	0	0	S	Rn				Rd			imm12														

```

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1');
(imm32, carry) = ARMEExpandImm_C(imm12, APSR.C);
    
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

ORR{S}{<c>}{<q>} {<Rd>}, <Rn>, #<const>

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>     See *Standard assembler syntax fields* on page F2-2415.
- <Rd>        The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions (T32)* on page F7-3066 or *SUBS PC, LR and related instructions (A32)* on page F7-3068.
- In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2296.
- <Rn>        The register that contains the operand. The PC can be used in A32 instructions.
- <const>     The immediate value to be bitwise ORed with the value obtained from <Rn>. See *Modified immediate constants in T32 instructions* on page F3-2444 or *Modified immediate constants in A32 instructions* on page F4-2472 for the range of values.

The pre-UAL syntax ORR<c>S is equivalent to ORRS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] OR imm32;
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

### F7.1.128 ORR (register)

Bitwise OR (register) performs a bitwise (inclusive) OR of a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

#### Encoding T1 ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

ORRS <Rdn>, <Rm> Outside IT block.  
 ORR<c> <Rdn>, <Rm> Inside IT block.

0	1	0	0	0	0	1	1	0	0	Rm	Rdn				

d = UInt(Rdn); n = UInt(Rdn); m = UInt(Rm); setflags = !InITBlock();  
 (shift\_t, shift\_n) = (SRTYPE\_LSL, 0);

#### Encoding T2 ARMv6T2, ARMv7

ORR{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	1	0	0	1	0	S	Rn				(0)	imm3			Rd			imm2		type	Rm					

if Rn == '1111' then SEE "Related encodings";  
 d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');  
 (shift\_t, shift\_n) = DecodeImmShift(type, imm3:imm2);  
 if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

#### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

ORR{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	0	1	1	0	0	S	Rn				Rd			imm5			type	0	Rm								

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;  
 d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');  
 (shift\_t, shift\_n) = DecodeImmShift(type, imm5);

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

**Related encodings** See *Move register and immediate shifts* on page F3-2457.

## Assembler syntax

ORR{S}{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift>}

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>      See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>        The destination register. If S is specified and <Rd> is the PC, see [SUBS PC, LR and related instructions \(T32\) on page F7-3066](#) or [SUBS PC, LR and related instructions \(A32\) on page F7-3068](#).  
In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
- <Rn>        The first operand register. The PC can be used in A32 instructions.
- <Rm>        The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.
- <shift>      The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. [Shifts applied to a register on page F2-2419](#) describes the shifts and how they are encoded.

In T32 assembly:

- Outside an IT block, if ORRS <Rd>, <Rn>, <Rd> is written with <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ORRS <Rd>, <Rn> had been written.
- Inside an IT block, if ORR<c> <Rd>, <Rn>, <Rd> is written with <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ORR<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax ORR<c>S is equivalent to ORRS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] OR shifted;
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

### F7.1.129 ORR (register-shifted register)

Bitwise OR (register-shifted register) performs a bitwise (inclusive) OR of a register value and a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

ORR{S}<C> <Rd>, <Rn>, <Rm>, <type> <Rs>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	1	0	0	S	Rn				Rd				Rs				0	type		1	Rm			

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

ORR{S}{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, <type> <Rs>

where:

S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<Rn> The first operand register.

<Rm> The register that is shifted and used as the second operand.

<type> The type of shift to apply to the value read from <Rm>. It must be one of:

ASR Arithmetic shift right, encoded as type = 0b10.

LSL Logical shift left, encoded as type = 0b00.

LSR Logical shift right, encoded as type = 0b01.

ROR Rotate right, encoded as type = 0b11.

<Rs> The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax ORR<c>S is equivalent to ORRS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] OR shifted;
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
    // APSR.V unchanged
```

### F7.1.130 PKH

Pack Halfword combines one halfword of its first operand with the other halfword of its shifted second operand.

#### Encoding T1 ARMv6T2, ARMv7

PKHBT<c> <Rd>, <Rn>, <Rm>{, LSL #<imm>}

PKHTB<c> <Rd>, <Rn>, <Rm>{, ASR #<imm>}

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

if S == '1' || T == '1' then UNDEFINED;
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); tbform = (tb == '1');
(shift_t, shift_n) = DecodeImmShift(tb:'0', imm3:imm2);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
    
```

#### Encoding A1 ARMv6\*, ARMv7

PKHBT<c> <Rd>, <Rn>, <Rm>{, LSL #<imm>}

PKHTB<c> <Rd>, <Rn>, <Rm>{, ASR #<imm>}

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	1	1	0	1	0	0	0		Rn		Rd		imm5		tb	0	1											Rm	

```

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); tbform = (tb == '1');
(shift_t, shift_n) = DecodeImmShift(tb:'0', imm5);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
    
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

PKHBT{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, LSL #<imm>}                   tbform == FALSE  
PKHTB{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, ASR #<imm>}                   tbform == TRUE

where:

<c>, <q>     See *Standard assembler syntax fields* on page F2-2415.  
<Rd>        The destination register.  
<Rn>        The first operand register.  
<Rm>        The register that is optionally shifted and used as the second operand.  
<imm>       The shift to apply to the value read from <Rm>, encoded in imm3:imm2 for encoding T1 and imm5 for encoding A1.

For PKHBT, it is one of:

- omitted**   No shift, encoded as 0b00000.
- 1-31**       Left shift by specified number of bits, encoded as a binary number.

For PKHTB, it is one of:

- omitted**   Instruction is a pseudo-instruction and is assembled as though PKHBT{<c>}{<q>} <Rd>, <Rm>, <Rn> had been written.
- 1-32**       Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b00000. Other shift amounts are encoded as binary numbers.

### ————— Note —————

An assembler can permit <imm> = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();

```

## F7.1.131 PLD, PLDW (immediate)

Preload Data signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the data cache.

On an architecture variant that includes both the PLD and PLDW instructions, the PLD instruction signals that the likely memory access is a read, and the PLDW instruction signals that it is a write.

The effect of a PLD or PLDW instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches on page E2-2340](#).

## Assembler syntax

PLD{W}{<C>}{<q>} [<Rn> {, #+/-<imm>}]

where:

W	If specified, selects PLDW, encoded as W = 1 in T32 encodings and R = 0 in A32 encodings. If omitted, selects PLD, encoded as W = 0 in T32 encodings and R = 1 in A32 encodings.
<C>, <q>	See <i>Standard assembler syntax fields</i> on page F2-2415. An A32 PLD or PLDW instruction must be unconditional.
<Rn>	The base register. The SP can be used. For PC use in the PLD instruction, see <i>PLD (literal)</i> on page F7-2748.
+/-	Is + or omitted to indicate that the immediate offset is added to the base register value (add == TRUE), or – to indicate that the offset is to be subtracted (add == FALSE). Different instructions are generated for #0 and #-0.
<imm>	The immediate offset used for forming the address. This offset can be omitted, meaning an offset of 0. Values are: <b>Encoding T1, A1</b> Any value in the range 0-4095. <b>Encoding T2</b> Any value in the range 0-255.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = if add then (R[n] + imm32) else (R[n] - imm32);
    if is_pldw then
        Hint_PreloadDataForWrite(address);
    else
        Hint_PreloadData(address);
```

### F7.1.132 PLD (literal)

Preload Data signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the data cache.

The effect of a PLD instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches on page E2-2340](#).

imm32 = ZeroExtend(imm12, 32); add = (U == '1');

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

PLD{<c>}{<q>} <label>	Normal form
PLD{<c>}{<q>} [PC, #+/-<imm>]	Alternative form

where:

<c>, <q>	See <a href="#">Standard assembler syntax fields on page F2-2415</a> . An A32 PLD instruction must be unconditional.
<label>	The label of the literal data item that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the <code>Align(PC, 4)</code> value of the instruction to this label. The offset must be in the range <code>-4095</code> to <code>4095</code> .  If the offset is zero or positive, <code>imm32</code> is equal to the offset and <code>add == TRUE</code> . If the offset is negative, <code>imm32</code> is equal to minus the offset and <code>add == FALSE</code> .
+/-	Is <code>+</code> or omitted to indicate that the immediate offset is added to the <code>Align(PC, 4)</code> value ( <code>add == TRUE</code> ), or <code>-</code> to indicate that the offset is to be subtracted ( <code>add == FALSE</code> ). Different instructions are generated for <code>#0</code> and <code>#-0</code> .
<imm>	The immediate offset used for forming the address. Values are in the range <code>0-4095</code> .

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of `0` that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2380](#).

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    Hint_PreloadData(address);
```

### F7.1.133 PLD, PLDW (register)

Preload Data signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the data cache.

On an architecture variant that includes both the PLD and PLDW instructions, the PLD instruction signals that the likely memory access is a read, and the PLDW instruction signals that it is a write.

The effect of a PLD or PLDW instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches on page E2-2340](#).

1	1	1	1	0	1	0	0	U	1	0	1			Rn			(1)	(1)	(1)	(1)												

n = UInt(Rn); imm32 = ZeroExtend(imm12, 32); add = (U == '1');

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

PLI{<c>}{<q>} [<Rn> {, #+/-<imm>}]	Immediate form
PLI{<c>}{<q>} <label>	Normal literal form
PLI{<c>}{<q>} [PC, #+/-<imm>]	Alternative literal form

where:

<c>, <q>	See <a href="#">Standard assembler syntax fields on page F2-2415</a> . An A32 PLI instruction must be unconditional.
<Rn>	Is the base register. The SP can be used.
+/-	Is + or omitted to indicate that the immediate offset is added to the base register value (add == TRUE), or – to indicate that the offset is to be subtracted (add == FALSE). Different instructions are generated for #0 and #-0.
<imm>	The immediate offset used for forming the address. For the immediate form of the syntax, <imm> can be omitted, in which case the #0 form of the instruction is assembled. Values are: <b>Encoding T1, T3, A1</b> Any value in the range 0 to 4095. <b>Encoding T2</b> Any value in the range 0 to 255.
<label>	The label of the instruction that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. The offset must be in the range –4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE. If the offset is negative, imm32 is equal to minus the offset and add == FALSE.

For the literal forms of the instruction, encoding T3 is used, or Rn is encoded as 0b1111 in encoding A1, to indicate that the PC is the base register.

The alternative literal syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2380](#).

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    Hint_PreloadInstr(address);
```

### F7.1.135 PLI (register)

Preload Instruction signals the memory system that instruction memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the instruction cache.

The effect of a PLI instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches on page E2-2340](#).

t = UInt(Rt); registers = Zeros(16); registers<t> = '1'; UnalignedAllowed = TRUE;
if t == 13 || (t == 15 && InITBlock() && !LastInITBlock()) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [POP \(T32\)](#) on page AppxA-4720.

## Assembler syntax

POP{<c>}{<q>} <registers> Standard syntax  
LDM{<c>}{<q>} SP!, <registers> Equivalent LDM syntax

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2426](#).

If the list contains more than one register, the instruction is assembled to encoding T1 or T2. If the list contains exactly one register, the instruction is assembled to encoding T1 or T3.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#). If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(13);
    address = SP;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = if UnalignedAllowed then MemU[address,4] else MemA[address,4];
            address = address + 4;
    if registers<15> == '1' then
        if UnalignedAllowed then
            if address<1:0> == '00' then
                LoadWritePC(MemU[address,4]);
            else
                UNPREDICTABLE;
        else
            LoadWritePC(MemA[address,4]);
    if registers<13> == '0' then SP = SP + 4*BitCount(registers);
    if registers<13> == '1' then SP = bits(32) UNKNOWN;
```

### F7.1.137 POP (A32)

```
t = UInt(Rt); registers = Zeros(16); registers<t> = '1'; UnalignedAllowed = TRUE;
// ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [POP \(A32\)](#) on page AppxA-4721.

## Assembler syntax

POP{<c>}{<q>} <registers> Standard syntax  
LDM{<c>}{<q>} SP!, <registers> Equivalent LDM syntax

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2426](#).

If the list contains more than one register, the instruction is assembled to encoding A1. If the list contains exactly one register, the instruction is assembled to encoding A2.

ARM deprecates any use of A32 instructions that include the SP, and the value of the SP after such an instruction is UNKNOWN.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).

ARM deprecates the use of this instruction with both the LR and the PC in the list.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(13);
    address = SP;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = if UnalignedAllowed then MemU[address,4] else MemA[address,4];
            address = address + 4;
    if registers<15> == '1' then
        if UnalignedAllowed then
            if address<1:0> == '00' then
                LoadWritePC(MemU[address,4]);
            else
                UNPREDICTABLE;
        else
            LoadWritePC(MemA[address,4]);
    if registers<13> == '0' then SP = SP + 4*BitCount(registers);
    if registers<13> == '1' then SP = bits(32) UNKNOWN;
```

## F7.1.138 PUSH

Push Multiple Registers stores multiple registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data.

**Encoding T1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7  
 PUSH<c> <registers>

```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [PUSH on page AppxA-4721](#).

## Assembler syntax

PUSH{<c>}{<q>} <registers> Standard syntax  
STMDB{<c>}{<q>} SP!, <registers> Equivalent STM syntax

where:

<c>, <q> See *Standard assembler syntax fields on page F2-2415*.

<registers> Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC on page F2-2426*.

If the list contains more than one register, the instruction is assembled to encoding T1, T2, or A1. If the list contains exactly one register, the instruction is assembled to encoding T1, T3, or A2.

The SP and PC can be in the list in A32 instructions, but not in T32 instructions. However:

- ARM deprecates the use of A32 instructions that include the PC in the list.
- If the SP is in the list, and it is not the lowest-numbered register in the list, the instruction stores an UNKNOWN value for the SP.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(13);
    address = SP - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            if i == 13 && i != LowestSetBit(registers) then // Only possible for encoding A1
                MemA[address,4] = bits(32) UNKNOWN;
            else
                if UnalignedAllowed then
                    MemU[address,4] = R[i];
                else
                    MemA[address,4] = R[i];
                address = address + 4;
    if registers<15> == '1' then // Only possible for encoding A1 or A2
        if UnalignedAllowed then
            MemU[address,4] = PCStoreValue();
        else
            MemA[address,4] = PCStoreValue();
    SP = SP - 4*BitCount(registers);
```

## F7.1.139 QADD

Saturating Add adds two register values, saturates the result to the 32-bit signed integer range  $-2^{31}$  to  $(2^{31} - 1)$ , and writes the result to the destination register. If saturation occurs, it sets the Q flag in the APSR.

### Encoding T1 ARMv6T2, ARMv7

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

QSAX{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<Rn> The first operand register.

<Rm> The second operand register.

The pre-UAL syntax QSUBADDX<c> is equivalent to QSAX<c>.

### Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    sum = SInt(R[n]<15:0>) + SInt(R[m]<31:16>);
    diff = SInt(R[n]<31:16>) - SInt(R[m]<15:0>);
    R[d]<15:0> = SignedSat(sum, 16);
    R[d]<31:16> = SignedSat(diff, 16);
    
```

## F7.1.146 QSUB

Saturating Subtract subtracts one register value from another register value, saturates the result to the 32-bit signed integer range  $-2^{31} \leq x \leq 2^{31} - 1$ , and writes the result to the destination register. If saturation occurs, it sets the Q flag in the APSR.

### Encoding T1 ARMv6T2, ARMv7

d = UInt(Rd); m = UInt(Rm); setflags = (S == '1');
(-, shift_n) = DecodeImmShift('11', imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

ROR{S}{<c>}{<q>} {<Rd>}, <Rm>, #<imm>

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q>     See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>        The destination register.  
In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
- <Rm>        The first operand register. The PC can be used in A32 instructions.
- <imm>       The shift amount, in the range 1 to 31. See [Shifts applied to a register on page F2-2419](#).

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry) = Shift_C(R[m], SRTYPE_ROR, shift_n, APSR.C);
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

## F7.1.155 ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The variable number of bits is read from the bottom byte of a register. It can optionally update the condition flags based on the result.

    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        // APSR.V unchanged
```

## F7.1.156 RRX

Rotate Right with Extend provides the value of the contents of a register shifted right by one place, with the Carry flag shifted into bit[31].

RRX can optionally update the condition flags based on the result. In that case, bit[0] is shifted into the Carry flag.

### Encoding T1 ARMv6T2, ARMv7

RRX{S}<c> <Rd>, <Rm>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

d = UInt(Rd); m = UInt(Rm); setflags = (S == '1');  
 if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

RRX{S}<c> <Rd>, <Rm>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
cond			0	0	0	1	1	0	1	S	(0)	(0)	(0)	(0)			Rd																Rm

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;  
 d = UInt(Rd); m = UInt(Rm); setflags = (S == '1');

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

RRX{S}{<c>}{<q>} {<Rd> ,} <Rm>

where:

S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q>     See [Standard assembler syntax fields on page F2-2415](#).

<Rd>        The destination register.

In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).

<Rm>        The register that contains the operand. The PC can be used in A32 instructions.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry) = Shift_C(R[m], SRTYPE_RRX, 1, APSR.C);
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

### F7.1.157 RSB (immediate)

Reverse Subtract (immediate) subtracts a register value from an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding T1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

cond		0	0	0	0	0	1	1	S	Rn				Rd				Rs		0	type		1	Rm							

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

RSB{S}<{c}>{<q>} {<Rd>}, <Rn>, <Rm>, <type> <Rs>

where:

S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<Rn> The first operand register.

<Rm> The register that is shifted and used as the second operand.

<type> The type of shift to apply to the value read from <Rm>. It must be one of:

ASR Arithmetic shift right, encoded as type = 0b10.

LSL Logical shift left, encoded as type = 0b00.

LSR Logical shift right, encoded as type = 0b01.

ROR Rotate right, encoded as type = 0b11.

<Rs> The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax RSB<c>S is equivalent to RSBS<c>.

### Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, nzcvc) = AddWithCarry(NOT(R[n]), shifted, '1');
    R[d] = result;
    if setflags then
        APSR.<N,Z,C,V> = nzcvc;
```

## F7.1.160 RSC (immediate)

Reverse Subtract with Carry (immediate) subtracts a register value and the value of NOT (Carry flag) from an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

RSC{S}<c> <Rd>, <Rn>, #<const>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	1	0	1	1	1	S	Rn				Rd				imm12												

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;  
 d = UInt(Rd); n = UInt(Rn); setflags = (S == '1'); imm32 = ARMEExpandImm(imm12);

### Assembler syntax

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

SBC{S}{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, <type> <Rs>

where:

S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<Rn> The first operand register.

<Rm> The register that is shifted and used as the second operand.

<type> The type of shift to apply to the value read from <Rm>. It must be one of:

ASR Arithmetic shift right, encoded as type = 0b10.

LSL Logical shift left, encoded as type = 0b00.

LSR Logical shift right, encoded as type = 0b01.

ROR Rotate right, encoded as type = 0b11.

<Rs> The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax SBC<c>S is equivalent to SBCS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, nzc) = AddWithCarry(R[n], NOT(shifted), APSR.C);
    R[d] = result;
    if setflags then
        APSR.<N,Z,C,V> = nzc;
```

## F7.1.169 SBFX

Signed Bit Field Extract extracts any number of adjacent bits at any position from a register, sign-extends them to 32 bits, and writes the result to the destination register.

### Encoding T1 ARMv6T2, ARMv7

SBFX<< <Rd>, <Rn>, #<lsb>, #<width>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	(0)	1	1	0	1	0	0	Rn			0	imm3			Rd			imm2(0)			widthm1						

```
d = UInt(Rd); n = UInt(Rn);
lsbit = UInt(imm3:imm2); widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

### Encoding A1 ARMv6T2, ARMv7

SBFX<< <Rd>, <Rn>, #<lsb>, #<width>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	1	1	1	1	0	1	widthm1			Rd			lsb			1 0 1			Rn										

```
d = UInt(Rd); n = UInt(Rn);
lsbit = UInt(lsb); widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [SBFX on page AppxA-4723](#).

## Assembler syntax

SBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register.
- <Rn> The first operand register.
- <lsb> Is the bit number of the least significant bit in the field, in the range 0-31. This determines the required value of `lsbit`.
- <width> Is the width of the field, in the range 1 to 32-`<lsb>`. The required value of `widthminus1` is `<width>-1`.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsbit + widthminus1;
    if msbit <= 31 then
        R[d] = SignExtend(R[n]<msbit:lsbit>, 32);
    else
        UNPREDICTABLE;
```

### F7.1.170 SDIV

Signed Divide divides a 32-bit signed integer register value by a 32-bit signed integer register value, and writes the result to the destination register. The condition flags are not affected.

**Encoding T1** ARMv7-R, ARMv7VE, otherwise OPTIONAL in ARMv7-A

SDIV<c> <Rd>, <Rn>, <Rm>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	1	1	0	0	1	Rn				(1)	(1)	(1)	(1)	Rd				1	1	1	1	Rm			

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);  
 if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

**Encoding A1** ARMv7VE, otherwise OPTIONAL in ARMv7-A and ARMv7-R

SDIV<c> <Rd>, <Rn>, <Rm>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	1	1	1	0	0	0	1	Rd				(1)	(1)	(1)	(1)	Rm				0	0	0	1	Rn					

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);  
 if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [SDIV on page AppxA-4724](#).

## Assembler syntax

SDIV{<C>}{<q>} {<Rd>}, <Rn>, <Rm>

where:

<C>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<Rn> The register that contains the dividend.

<Rm> The register that contains the divisor.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if SInt(R[m]) == 0 then
        if IntegerZeroDivideTrappingEnabled() then
            GenerateIntegerZeroDivide();
        else
            result = 0;
    else
        result = RoundTowardsZero(SInt(R[n]) / SInt(R[m]));
    R[d] = result<31:0>;
```

## Overflow

If the signed integer division  $0x80000000 / 0xFFFFFFFF$  is performed, the pseudocode produces the intermediate integer result  $+2^{31}$ , that overflows the 32-bit signed integer range. No indication of this overflow case is produced, and the 32-bit result written to R[d] must be the bottom 32 bits of the binary representation of  $+2^{31}$ . So the result of the division is  $0x80000000$ .

## F7.1.171 SEL

Select Bytes selects each byte of its result from either its first operand or its second operand, according to the values of the GE flags.

### Encoding T1 ARMv6T2, ARMv7

SEL<c> <Rd>, <Rn>, <Rm>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

SEL{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register.
- <Rn> The first operand register.
- <Rm> The second operand register.

### Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    R[d]<7:0> = if APSR.GE<0> == '1' then R[n]<7:0> else R[m]<7:0>;
    R[d]<15:8> = if APSR.GE<1> == '1' then R[n]<15:8> else R[m]<15:8>;
    R[d]<23:16> = if APSR.GE<2> == '1' then R[n]<23:16> else R[m]<23:16>;
    R[d]<31:24> = if APSR.GE<3> == '1' then R[n]<31:24> else R[m]<31:24>;
    
```

## F7.1.172 SETEND

Set Endianness writes a new value to ENDIANSTATE.

### Encoding T1 ARMv6\*, ARMv7

SETEND <endian\_specifier>

Not permitted in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	0	1	1	0	0	1	0	(1)	E	(0)	(0)	(0)

set\_bigend = (E == '1');  
 if InITBlock() then UNPREDICTABLE;

### Encoding A1 ARMv6\*, ARMv7

SETEND <endian\_specifier>

Cannot be conditional

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	0	1	0	0	0	0	(0)	(0)	(0)	1	(0)	(0)	(0)	(0)	(0)	(0)	E	(0)	0	0	0	0	(0)	(0)	(0)	(0)

set\_bigend = (E == '1');

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

SETEND{<q>} <endian\_specifier>

where:

<q> See [Standard assembler syntax fields on page F2-2415](#). A SETEND instruction must be unconditional.

<endian\_specifier>

Is one of:

BE Sets the E bit in the instruction. This sets ENDIANSTATE.

LE Clears the E bit in the instruction. This clears ENDIANSTATE.

### Operation

EncodingSpecificOperations();  
 ENDIANSTATE = if set\_bigend then '1' else '0';

## F7.1.173 SEV

Send Event is a hint instruction. It causes an event to be signaled to all PEs in the multiprocessor system. For more information, see [Wait For Event and Send Event](#) on page G1-3460.

**Encoding T1** ARMv7 (executes as NOP in ARMv6T2)

SEV<c>

```

### F7.1.181 SMC (previously SMI)

Secure Monitor Call is a system instruction. For details see [SMC \(previously SMI\)](#) on page F7-3058.

### F7.1.182 SMLABB, SMLABT, SMLATB, SMLATT

Signed Multiply Accumulate (halfwords) performs a signed multiply accumulate operation. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is added to a 32-bit accumulate value and the result is written to the destination register.

If overflow occurs during the addition of the accumulate value, the instruction sets the Q flag in the APSR. It is not possible for overflow to occur during the multiplication.

## Assembler syntax

SMLA<x><y>{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

where:

- <x> Specifies which half of the source register <Rn> is used as the first multiply operand. If <x> is B, then the bottom half (bits[15:0]) of <Rn> is used. If <x> is T, then the top half (bits[31:16]) of <Rn> is used.
- <y> Specifies which half of the source register <Rm> is used as the second multiply operand. If <y> is B, then the bottom half (bits[15:0]) of <Rm> is used. If <y> is T, then the top half (bits[31:16]) of <Rm> is used.
- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register.
- <Rn> The source register whose bottom or top half (selected by <x>) is the first multiply operand.
- <Rm> The source register whose bottom or top half (selected by <y>) is the second multiply operand.
- <Ra> The register that contains the accumulate value.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = if n_high then R[n]<31:16> else R[n]<15:0>;
    operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
    result = SInt(operand1) * SInt(operand2) + SInt(R[a]);
    R[d] = result<31:0>;
    if result != SInt(result<31:0>) then // Signed overflow
        APSR.Q = '1';
```

## F7.1.183 SMLAD

Signed Multiply Accumulate Dual performs two signed  $16 \times 16$ -bit multiplications. It adds the products to a 32-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top  $\times$  bottom and bottom  $\times$  top multiplication.

This instruction sets the Q flag if the accumulate operation overflows. Overflow cannot occur during the multiplications.

### Encoding T1 ARMv6T2, ARMv7

if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

SMLAD{X}{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

where:

- X            If X is present (encoded as M = 1), the multiplications are bottom × top and top × bottom.  
              If the X is omitted (encoded as M = 0), the multiplications are bottom × bottom and top × top.
- <c>, <q>      See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>         The destination register.
- <Rn>         The first operand register.
- <Rm>         The second operand register.
- <Ra>         The register that contains the accumulate value.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = if m_swap then ROR(R[m],16) else R[m];
    product1 = SInt(R[n]<15:0>) * SInt(operand2<15:0>);
    product2 = SInt(R[n]<31:16>) * SInt(operand2<31:16>);
    result = product1 + product2 + SInt(R[a]);
    R[d] = result<31:0>;
    if result != SInt(result<31:0>) then // Signed overflow
        APSR.Q = '1';
```

## F7.1.184 SMLAL

Signed Multiply Accumulate Long multiplies two signed 32-bit values to produce a 64-bit value, and accumulates this with a 64-bit value.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *SMLAL* on page AppxA-4725.

## Assembler syntax

SMLAL{S}{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.  
S can be specified only for the A32 instruction set.
- <c>, <q>     See [Standard assembler syntax fields on page F2-2415](#).
- <RdLo>      Supplies the lower 32 bits of the accumulate value, and is the destination register for the lower 32 bits of the result.
- <RdHi>      Supplies the upper 32 bits of the accumulate value, and is the destination register for the upper 32 bits of the result.
- <Rn>        The first operand register.
- <Rm>        The second operand register.

The pre-UAL syntax SMLAL<c>S is equivalent to SMLALS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = SInt(R[n]) * SInt(R[m]) + SInt(R[dHi]:R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
    if setflags then
        APSR.N = result<63>;
        APSR.Z = IsZeroBit(result<63:0>);
        // APSR.C, APSR.V unchanged
```

## F7.1.185 SMLALBB, SMLALBT, SMLALTB, SMLALTT

Signed Multiply Accumulate Long (halfwords) multiplies two signed 16-bit values to produce a 32-bit value, and accumulates this with a 64-bit value. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is sign-extended and accumulated with a 64-bit accumulate value.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected if it occurs. Instead, the result wraps around modulo  $2^{64}$ .

    R[dLo] = result<31:0>;
```

## F7.1.187 SMLAWB, SMLAWT

Signed Multiply Accumulate (word by halfword) performs a signed multiply accumulate operation. The multiply acts on a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are added to a 32-bit accumulate value and the result is written to the destination register. The bottom 16 bits of the 48-bit product are ignored.

If overflow occurs during the addition of the accumulate value, the instruction sets the Q flag in the APSR. No overflow can occur during the multiplication.

    result = (SInt(R[a]) << 32) - SInt(R[n]) * SInt(R[m]);
    if round then result = result + 0x80000000;
    R[d] = result<63:32>;
```

## F7.1.192 SMMUL

Signed Most Significant Word Multiply multiplies two signed 32-bit values, extracts the most significant 32 bits of the result, and writes those bits to the destination register.

Optionally, the instruction can specify that the result is rounded instead of being truncated. In this case, the constant  $0x80000000$  is added to the product before the high word is extracted.

### Encoding T1 ARMv6T2, ARMv7

 if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

SMMUL{R}{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

where:

- R            If R is present, the multiplication is rounded.  
              If the R is omitted, the multiplication is truncated.
- <c>, <q>     See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>        The destination register.
- <Rn>        The first operand register.
- <Rm>        The second operand register.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = SInt(R[n]) * SInt(R[m]);
    if round then result = result + 0x80000000;
    R[d] = result<63:32>;
```

### F7.1.193 SMUAD

Signed Dual Multiply Add performs two signed  $16 \times 16$ -bit multiplications. It adds the products together, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top  $\times$  bottom and bottom  $\times$  top multiplication.

This instruction sets the Q flag if the addition overflows. The multiplications cannot overflow.

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

SMUL<x><y>{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

where:

- <x> Specifies which half of the source register <Rn> is used as the first multiply operand. If <x> is B, then the bottom half (bits[15:0]) of <Rn> is used. If <x> is T, then the top half (bits[31:16]) of <Rn> is used.
- <y> Specifies which half of the source register <Rm> is used as the second multiply operand. If <y> is B, then the bottom half (bits[15:0]) of <Rm> is used. If <y> is T, then the top half (bits[31:16]) of <Rm> is used.
- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register.
- <Rn> The source register whose bottom or top half (selected by <x>) is the first multiply operand.
- <Rm> The source register whose bottom or top half (selected by <y>) is the second multiply operand.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = if n_high then R[n]<31:16> else R[n]<15:0>;
    operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
    result = SInt(operand1) * SInt(operand2);
    R[d] = result<31:0>;
    // Signed overflow cannot occur
```

## F7.1.195 SMULL

Signed Multiply Long multiplies two 32-bit signed values to produce a 64-bit result.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

### Encoding T1 ARMv6T2, ARMv7

if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *SMULL* on page AppxA-4724.

## Assembler syntax

SMULL{S}{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

where:

S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.  
S can be specified only for the A32 instruction set.

<c>, <q>     See *Standard assembler syntax fields* on page F2-2415.

<RdLo>      Stores the lower 32 bits of the result.

<RdHi>      Stores the upper 32 bits of the result.

<Rn>        The first operand register.

<Rm>        The second operand register.

The pre-UAL syntax SMULL<c>S is equivalent to SMULLS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = SInt(R[n]) * SInt(R[m]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
    if setflags then
        APSR.N = result<63>;
        APSR.Z = IsZeroBit(result<63:0>);
        // APSR.C, APSR.V unchanged
```

### F7.1.196 SMULWB, SMULWT

Signed Multiply (word by halfword) multiplies a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are written to the destination register. The bottom 16 bits of the 48-bit product are ignored. No overflow is possible during this instruction.

    product = SInt(R[n]) * SInt(operand2);
    R[d] = product<47:16>;
    // Signed overflow cannot occur
```

## F7.1.197 SMUSD

Signed Multiply Subtract Dual performs two signed  $16 \times 16$ -bit multiplications. It subtracts one of the products from the other, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top  $\times$  bottom and bottom  $\times$  top multiplication.

Overflow cannot occur.

if d == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

SSAT{<c>}{<q>} <Rd>, #<imm>, <Rn> {, <shift>}

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register.
- <imm> The bit position for saturation, in the range 1 to 32. The sat\_imm field of the instruction encodes this bit position, by taking the value (<imm>-1).
- <Rn> The register that contains the value to be saturated.
- <shift> The optional shift, encoded in the sh bit and the immsh field, where immsh is:
- imm3:imm2 for encoding T1.
  - imm5 for encoding A1.
- <shift> must be one of:
- omitted** No shift. Encoded as sh = 0, immsh = 0b00000.
- LSL #<n> Left shift by <n> bits, with <n> in the range 1-31.  
Encoded as sh = 0, immsh = <n>.
- ASR #<n> Arithmetic right shift by <n> bits, with <n> in the range 1-31.  
Encoded as sh = 1, immsh = <n>.
- ASR #32 Arithmetic right shift by 32 bits, permitted only for encoding A1.  
Encoded as sh = 1, immsh = 0b00000.

### Note

An assembler can permit ASR #0 or LSL #0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand = Shift(R[n], shift_t, shift_n, APSR.C); // APSR.C ignored
    (result, sat) = SignedSatQ(SInt(operand), saturate_to);
    R[d] = SignExtend(result, 32);
    if sat then
        APSR.Q = '1';
```

## F7.1.200 SSAT16

Signed Saturate 16 saturates two signed 16-bit values to a selected signed range.

The Q flag is set if the operation saturates.

    APSR.GE<3:2> = if diff2 >= 0 then '11' else '00';
```

## F7.1.204 STC, STC2

Store Coprocessor stores data from a coprocessor to a sequence of consecutive memory addresses. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the D bit, the CRd field, and in the Unindexed addressing mode only, the imm8 field. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid STC and STC2 instructions when coproc is in the range p8-p15. For more information see [Coprocessor support on page E1-2331](#).

In an implementation that includes EL2, the permitted STC access to a system control register can be trapped to Hyp mode, meaning that an attempt to execute an STC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [Trapping general CP14 accesses to debug registers on page G1-3515](#).

### ———— Note ————

For simplicity, the STC pseudocode does not show this possible trap to Hyp mode.

d = UInt(Rd); t = UInt(Rt); n = UInt(Rn);  
 if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;  
 if d == n || d == t then UNPREDICTABLE;

### Encoding A1 ARMv8

STLEX <Rd>, <Rt>, [<Rn>]

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	1	0	0	0	Rn				Rd				(1)	(1)	1	0	1	0	0	1	Rt			

d = UInt(Rd); t = UInt(Rt); n = UInt(Rn);  
 if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;  
 if d == n || d == t then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

STLEX{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register for the returned status value. The value returned is:  
0 If the operation updates memory.  
1 If the operation fails to update memory.
- <Rt> The source register.
- <Rn> The base register. The SP can be used.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,4) then
        acctype = AccType_ORDERED;
        aligned = (address == Align(address, 4));
        MemA_with_type[address, 4, acctype, aligned] = R[t];
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

## Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

If [SCTLR.A](#) and [SCTLR.U](#) are both 0, a non word-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

## F7.1.208 STLEXB

Store Release Exclusive Byte stores a byte from a register to memory if the executing PE has exclusive access to the memory addressed. The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#) on page E2-2355.

For more information about support for shared memory see [Synchronization and semaphores](#) on page E2-2369. For information about memory accesses see [Memory accesses](#) on page F2-2422.

 if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;  
 if d == n || d == t then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

STLEXB{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register for the returned status value. The value returned is:  
0 If the operation updates memory.  
1 If the operation fails to update memory.
- <Rt> The source register.
- <Rn> The base register. The SP can be used.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,1) then
        acctype = AccType_ORDERED;
        aligned = TRUE;
        MemA_with_type[address, 1, acctype, aligned] = R[t]<7:0>;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

## Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

If ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

## F7.1.209 STLEXD

Store Release Exclusive Dual stores a doubleword from two registers to memory if the executing PE has exclusive access to the memory addressed. The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#) on page E2-2355.

For more information about support for shared memory see [Synchronization and semaphores](#) on page E2-2369. For information about memory accesses see [Memory accesses](#) on page F2-2422.

### Encoding T1 ARMv8

1	1	1	0	1	0	0	0	1	1	0	0	Rn				Rt				Rt2				1	1	1	1	Rd			

d = UInt(Rd); t = UInt(Rt); t2 = UInt(Rt2); n = UInt(Rn);  
 if d == 15 || t == 15 || t2 == 15 || n == 15 then UNPREDICTABLE;  
 if d == n || d == t || d == t2 then UNPREDICTABLE;

### Encoding A1 ARMv8

STLEXD <Rd>, <Rt>, <Rt2>, [<Rn>]

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	1	0	1	0	Rn				Rd				(1)	(1)	1	0	1	0	0	1	Rt			

d = UInt(Rd); t = UInt(Rt); t2 = t+1; n = UInt(Rn);  
 if d == 15 || Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;  
 if d == n || d == t || d == t2 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [STLEXD](#) on page AppxA-4742.

## Assembler syntax

STLEXD{<c>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

where:

- <c>, <q> See *Standard assembler syntax fields on page F2-2415*.
- <Rd> The destination register for the returned status value. The value returned is:  
0 If the operation updates memory.  
1 If the operation fails to update memory.
- <Rt> The first source register. For an A32 instruction, <Rt> must be even-numbered and not R14.
- <Rt2> The second source register. For an A32 instruction, <Rt2> must be <R(t+1)>.
- <Rn> The base register. The SP can be used.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n];
    // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
    value = if BigEndian() then R[t]:R[t2] else R[t2]:R[t];
    if AArch32.ExclusiveMonitorsPass(address, 8) then
        acctype = AccType_ORDERED;
        aligned = (address == Align(address, 8));
        MemA_with_type[address, 8, acctype, aligned] = value;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

## Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

If **SCTLR.A** and **SCTLR.U** are both 0, a non word-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

## F7.1.210 STLEXH

Store Release Exclusive Halfword stores a halfword from a register to memory if the executing PE has exclusive access to the memory addressed. The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#) on page E2-2355.

For more information about support for shared memory see [Synchronization and semaphores](#) on page E2-2369. For information about memory accesses see [Memory accesses](#) on page F2-2422.

### Encoding T1 ARMv8

 if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;  
 if d == n || d == t then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

STLEXH{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register for the returned status value. The value returned is:  
0 If the operation updates memory.  
1 If the operation fails to update memory.
- <Rt> The source register.
- <Rn> The base register. The SP can be used.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,2) then
        acctype = AccType_ORDERED;
        aligned = (address == Align(address, 2));
        MemA_with_type[address, 2, acctype, aligned] = R[t]<15:0>;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

## Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- memory is not updated
- <Rd> is not updated.

If [SCTLR.A](#) and [SCTLR.U](#) are both 0, a non word-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

## F7.1.211 STLH

Store Release Halfword stores a halfword from a register to memory. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2355.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2369. For information about memory accesses see *Memory accesses* on page F2-2422.

n = UInt(Rn); registers = '0':M:'0':register\_list; wback = (W == '1');  
 if n == 15 || BitCount(registers) < 2 then UNPREDICTABLE;  
 if wback && registers<n> == '1' then UNPREDICTABLE;

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

STM<c> <Rn>{!}, <registers>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		1	0	0	0	1	0	W	0	Rn	register_list																				

n = UInt(Rn); registers = register\_list; wback = (W == '1');  
 if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [STM \(STMIA, STMEA\) on page AppxA-4727](#).

#### ThumbEE instructions

ARM deprecates any use of ThumbEE instructions and they are not documented in this manual.

## Assembler syntax

STM{<c>}{<q>} <Rn>{!}, <registers>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rn> The base register. The SP can be used.

! Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1.  
If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.

<registers> Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2426](#).

Encoding T2 does not support a list containing only one register. If an STM instruction with just one register <Rt> in the list is assembled to T32 and encoding T1 is not available, it is assembled to the equivalent STR{<c>}{<q>} <Rt>, [<Rn>]{, #4} instruction.

The SP and PC can be in the list in A32 instructions, but not in T32 instructions. However, ARM deprecates the use of A32 instructions that include the SP or the PC in the list.

ARM deprecates the use of instructions with the base register in the list and ! specified. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

An instruction with the base register in the list and ! specified cannot use encoding T2.

STMEA and STMIA are pseudo-instructions for STM. STMEA refers to its use for pushing data onto Empty Ascending stacks.

The pre-UAL syntaxes STM<c>IA and STM<c>EA are equivalent to STM<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN; // Only possible for encodings T1 and A1
            else
                MemA[address,4] = R[i];
                address = address + 4;
    if registers<15> == '1' then // Only possible for encoding A1
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] + 4*BitCount(registers);
```

### F7.1.213 STMDA (STMED)

Store Multiple Decrement After (Store Multiple Empty Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

For details of related system instructions see [STM \(User registers\)](#) on page F7-3064.

#### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

STMDA<c> <Rn>{!}, <registers>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		1	0	0	0	0	0	0	W	0	Rn						register_list														

```
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [STMDA \(STMED\)](#) on page AppxA-4727.

## Assembler syntax

STMDA{<c>}{<q>} <Rn>{!}, <registers>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rn> The base register. The SP can be used.
- ! Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1.  
If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.
- <registers> Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2426](#).
- The SP and PC can be in the list. However, instructions that include the SP or the PC in the list are deprecated.
- ARM deprecates the use of instructions with the base register in the list and ! specified. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

STMED is a pseudo-instruction for STMDA, referring to its use for pushing data onto Empty Descending stacks.

The pre-UAL syntaxes STM<c>DA and STM<c>ED are equivalent to STMDA<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers) + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;
            else
                MemA[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] - 4*BitCount(registers);
```

## F7.1.214 STMDB (STMTD)

Store Multiple Decrement Before (Store Multiple Full Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the first of those locations can optionally be written back to the base register.

For details of related system instructions see *STM (User registers)* on page F7-3064.

### Encoding T1 ARMv6T2, ARMv7

STMDB<c> <Rn>{!}, <registers>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	1	0	0	W	0	Rn				(0)	M	(0)	register_list												

if W == '1' && Rn == '1101' then SEE PUSH;  
 n = UInt(Rn); registers = '0':M:'0':register\_list; wback = (W == '1');  
 if n == 15 || BitCount(registers) < 2 then UNPREDICTABLE;  
 if wback && registers<n> == '1' then UNPREDICTABLE;

### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

STMDB<c> <Rn>{!}, <registers>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		1	0	0	1	0	0	W	0	Rn				register_list																	

if W == '1' && Rn == '1101' && BitCount(register\_list) >= 2 then SEE PUSH;  
 n = UInt(Rn); registers = register\_list; wback = (W == '1');  
 if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *STMDB (STMTD)* on page AppxA-4728.

## Assembler syntax

STMDB{<c>}{<q>} <Rn>{!}, <registers>

where:

<c>, <q> See *Standard assembler syntax fields on page F2-2415*.

<Rn> The base register. The SP can be used. If the SP is used, and ! is specified:

- For encoding T1, it is treated as described in *PUSH on page F7-2760*.
- For encoding A1, if there is more than one register in the <registers> list, it is treated as described in *PUSH on page F7-2760*.

! Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1.

If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.

<registers> Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC on page F2-2426*.

Encoding T1 does not support a list containing only one register. If an STMDB instruction with just one register <Rt> in the list is assembled to T32, it is assembled to the equivalent STR{<c>}{<q>} <Rt>, [<Rn>, #-4]{!} instruction.

The SP and PC can be in the list in A32 instructions, but not in T32 instructions. However, ARM deprecates the use of A32 instructions that include the SP or the PC in the list.

Instructions with the base register in the list and ! specified are only available in the A32 instruction set, and ARM deprecates the use of such instructions. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

STMPD is a pseudo-instruction for STMDB, referring to its use for pushing data onto Full Descending stacks.

The pre-UAL syntaxes STM<c>DB and STM<c>FD are equivalent to STMDB<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n] - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN; // Only possible for encoding A1
            else
                MemA[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then // Only possible for encoding A1
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] - 4*BitCount(registers);
```

### F7.1.215 STMIB (STMFA)

Store Multiple Increment Before (Store Multiple Full Ascending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register.

For details of related system instructions see [STM \(User registers\)](#) on page F7-3064.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

STMIB<c> <Rn>{!}, <registers>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		1	0	0	1	1	0	W	0	Rn								register_list													

```
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [STMIB \(STMFA\)](#) on page AppxA-4728.

## Assembler syntax

STMIB{<c>}{<q>} <Rn>{!}, <registers>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rn> The base register. The SP can be used.
- ! Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1.  
If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.
- <registers> Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2426](#).
- The SP and PC can be in the list. However, instructions that include the SP or the PC in the list are deprecated.
- ARM deprecates the use of instructions with the base register in the list and ! specified. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

STMFA is a pseudo-instruction for STMIB, referring to its use for pushing data onto Full Ascending stacks.

The pre-UAL syntax STM<c>IB and STM<c>FA are equivalent to STMIB<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;
            else
                MemA[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] + 4*BitCount(registers);
```

## F7.1.216 STR (immediate, T32)

Store Register (immediate) calculates an address from a base register value and an immediate offset, and stores a word from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses on page F2-2422](#).

**Encoding T1** ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

## Assembler syntax

STR{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]	Offset: index==TRUE, wback==FALSE
STR{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!	Pre-indexed: index==TRUE, wback==TRUE
STR{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>	Post-indexed: index==FALSE, wback==TRUE

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rt> The source register. The SP can be used.

<Rn> The base register. The SP can be used.

+/- Is + or omitted if the immediate offset is to be added to the base register value (add == TRUE), or – if it is to be subtracted (add == FALSE). #0 and #-0 generate different instructions.

<imm> The immediate offset used for forming the address. Values are:

<b>Encoding T1</b>	Multiples of 4 in the range 0-124.
<b>Encoding T2</b>	Multiples of 4 in the range 0-1020.
<b>Encoding T3</b>	Any value in the range 0-4095.
<b>Encoding T4</b>	Any value in the range 0-255.

For the offset addressing syntax, <imm> can be omitted, meaning an offset of 0.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,4] = R[t];
    if wback then R[n] = offset_addr;
```

### F7.1.217 STR (immediate, A32)

Store Register (immediate) calculates an address from a base register value and an immediate offset, and stores a word from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses on page F2-2422](#).

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    MemU[address,1] = R[t]<7:0>;
    if wback then R[n] = offset_addr;
```

## F7.1.222 STRBT

Store Register Byte Unprivileged stores a byte from a register to memory. For information about memory accesses see [Memory accesses on page F2-2422](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

### Encoding T1 ARMv6T2, ARMv7

## Assembler syntax

STRBT{<c>}{<q>} <Rt>, [<Rn> {, #<imm>}]	Offset: T32 only
STRBT{<c>}{<q>} <Rt>, [<Rn>] {, #<imm>}	Post-indexed: A32 only
STRBT{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm> {, <shift>}	Post-indexed: A32 only

where:

<c>, <q>	See <a href="#">Standard assembler syntax fields on page F2-2415</a> .
<Rt>	The source register.
<Rn>	The base register. The SP can be used.
+/-	Is + or omitted if <imm> or the optionally shifted value of <Rm> is to be added to the base register value (add == TRUE), or – if it is to be subtracted (permitted in A32 instructions only, add == FALSE).
<imm>	The immediate offset applied to the value of <Rn>. Values are 0-255 for encoding T1, and 0-4095 for encoding A1. <imm> can be omitted, meaning an offset of 0.
<Rm>	Contains the offset that is optionally shifted and added to the value of <Rn> to form the address.
<shift>	The shift to apply to the value read from <Rm>. If omitted, no shift is applied. <a href="#">Shifts applied to a register on page F2-2419</a> describes the shifts and how they are encoded.

The pre-UAL syntax STR<c>BT is equivalent to STRBT<c>.

## Operation

 if d == n || d == t then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [STREX on page AppxA-4740](#).

## Assembler syntax

STREX{<c>}{<q>} <Rd>, <Rt>, [<Rn> {, #<imm>}]

where:

- <c>, <q> See *Standard assembler syntax fields on page F2-2415*.
- <Rd> The destination register for the returned status value. The value returned is:  
0 If the operation updates memory.  
1 If the operation fails to update memory.
- <Rt> The source register.
- <Rn> The base register. The SP can be used.
- <imm> The immediate offset added to the value of <Rn> to form the address. Values are multiples of 4 in the range 0-1020 for encoding T1, and 0 for encoding A1. <imm> can be omitted, meaning an offset of 0.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n] + imm32;
    if AArch32.ExclusiveMonitorsPass(address,4) then
        MemA[address,4] = R[t];
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

## Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

If **SCTLR.A** and **SCTLR.U** are both 0, a non word-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

## F7.1.226 STREXB

Store Register Exclusive Byte derives an address from a base register value, and stores a byte from a register to memory if the executing PE has exclusive access to the memory addressed.

For more information about support for shared memory see [Synchronization and semaphores on page E2-2369](#). For information about memory accesses see [Memory accesses on page F2-2422](#).

### Encoding T1 ARMv7

d = UInt(Rd); t = UInt(Rt); n = UInt(Rn);  
 if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;  
 if d == n || d == t then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [STREXB on page AppxA-4740](#).

## Assembler syntax

STREXB{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register for the returned status value. The value returned is:  
0 If the operation updates memory.  
1 If the operation fails to update memory.

<Rt> The source register.

<Rn> The base register. The SP can be used.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,1) then
        MemA[address,1] = R[t]<7:0>;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

## Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

If ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

## F7.1.227 STREXD

Store Register Exclusive Doubleword derives an address from a base register value, and stores a 64-bit doubleword from two registers to memory if the executing PE has exclusive access to the memory addressed.

if d == 15 || Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t || d == t2 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [STREXD on page AppxA-4741](#).

## Assembler syntax

STREXD{<c>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register for the returned status value. The value returned is:  
0 If the operation updates memory.  
1 If the operation fails to update memory.  
<Rd> must not be the same as <Rn>, <Rt>, or <Rt2>.
- <Rt> The first source register. For an A32 instruction, <Rt> must be even-numbered and not R14.
- <Rt2> The second source register. For an A32 instruction, <Rt2> must be <R(t+1)>.
- <Rn> The base register. The SP can be used.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n];
    // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
    value = if BigEndian() then R[t]:R[t2] else R[t2]:R[t];
    if AArch32.ExclusiveMonitorsPass(address,8) then
        MemA[address,8] = value; R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

## Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

If [SCTLR.A](#) and [SCTLR.U](#) are both 0, a non doubleword-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non doubleword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If [ExclusiveMonitorsPass\(\)](#) returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If [ExclusiveMonitorsPass\(\)](#) returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

## F7.1.228 STREXH

Store Register Exclusive Halfword derives an address from a base register value, and stores a halfword from a register to memory if the executing PE has exclusive access to the memory addressed.

STREXH{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register for the returned status value. The value returned is:  
0 If the operation updates memory.  
1 If the operation fails to update memory.
- <Rt> The source register.
- <Rn> The base register. The SP can be used.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,2) then
        MemA[address,2] = R[t]<15:0>;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

## Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

If [SCTLR.A](#) and [SCTLR.U](#) are both 0, a non halfword-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If [ExclusiveMonitorsPass\(\)](#) returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If [ExclusiveMonitorsPass\(\)](#) returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

### F7.1.229 STRH (immediate, T32)

Store Register Halfword (immediate) calculates an address from a base register value and an immediate offset, and stores a halfword from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses on page F2-2422](#).

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [STRH \(register\) on page AppxA-4736](#).

### Modified operation in ThumbEE

ARM deprecates any use of ThumbEE instructions and they are not documented in this manual.

## Assembler syntax

STRH{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>{, LSL #<imm>}] Offset: index==TRUE, wback==FALSE  
STRH{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>! Pre-indexed: index==TRUE, wback==TRUE  
STRH{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm> Post-indexed: index==FALSE, wback==TRUE

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).  
<Rt> The source register.  
<Rn> The base register. The SP can be used. In the A32 instruction set, for offset addressing only, the PC can be used. However, ARM deprecates use of the PC.  
+/- Is + or omitted if the optionally shifted value of <Rm> is to be added to the base register value (add == TRUE), or – if it is to be subtracted (permitted in A32 instructions only, add == FALSE).  
<Rm> Contains the offset that is optionally left shifted and added to the value of <Rn> to form the address.  
<imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. Only encoding T2 is permitted, and <imm> is encoded in imm2.  
If absent, no shift is specified and all encodings are permitted. In encoding T2, imm2 is encoded as 0b00.

The pre-UAL syntax STR<c>H is equivalent to STRH<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    MemU[address,2] = R[t]<15:0>;
    if wback then R[n] = offset_addr;
```

## F7.1.232 STRHT

Store Register Halfword Unprivileged stores a halfword from a register to memory. For information about memory accesses see [Memory accesses on page F2-2422](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

### Encoding T1 ARMv6T2, ARMv7

    MemU_unpriv[address,2] = R[t]<15:0>;
    if postindex then R[n] = offset_addr;
```

### F7.1.233 STRT

Store Register Unprivileged stores a word from a register to memory. For information about memory accesses see [Memory accesses on page F2-2422](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

 d = UInt(Rd); n = UInt(Rn); setflags = FALSE; imm32 = ZeroExtend(i:imm3:imm8, 32);  
 if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

SUB{S}{<c>}{<q>} {<Rd>}, <Rn>, #<const> All encodings permitted  
SUBW{<c>}{<q>} {<Rd>}, <Rn>, #<const> Only encoding T4 permitted

where:

- S If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register. If S is specified and <Rd> is the PC, see [SUBS PC, LR and related instructions \(T32\) on page F7-3066](#) or [SUBS PC, LR and related instructions \(A32\) on page F7-3068](#).
- <Rn> The first operand register. If the SP is specified for <Rn>, see [SUB \(SP minus immediate\) on page F7-2922](#). If the PC is specified for <Rn>, see [ADR on page F7-2554](#).
- <const> The immediate value to be subtracted from the value obtained from <Rn>. The range of values is 0-7 for encoding T1, 0-255 for encoding T2 and 0-4095 for encoding T4. See [Modified immediate constants in T32 instructions on page F3-2444](#) for the range of values for encoding T3.
- When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4. If encoding T4 is required, use the SUBW syntax. Encoding T1 is preferred to encoding T2 if <Rd> is specified and encoding T2 is preferred to encoding T1 if <Rd> is omitted.

The pre-UAL syntax SUB<c>S is equivalent to SUBS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzc) = AddWithCarry(R[n], NOT(imm32), '1');
    R[d] = result;
    if setflags then
        APSR.<N,Z,C,V> = nzc;
```

### F7.1.235 SUB (immediate, A32)

This instruction subtracts an immediate value from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

SUB{S}{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, <type> <Rs>

where:

S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q>     See [Standard assembler syntax fields on page F2-2415](#).

<Rd>        The destination register.

<Rn>        The first operand register.

<Rm>        The register that is shifted and used as the second operand.

<type>      The type of shift to apply to the value read from <Rm>. It must be one of:

ASR        Arithmetic shift right, encoded as type = 0b10.

LSL        Logical shift left, encoded as type = 0b00.

LSR        Logical shift right, encoded as type = 0b01.

ROR        Rotate right, encoded as type = 0b11.

<Rs>        The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax SUB<c>S is equivalent to SUBS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

SUB{S}{<c>}{<q>} {<Rd>}, SP, <Rm> {, <shift>}

where:

- S            If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
- <c><q>        See [Standard assembler syntax fields on page F2-2415](#).
- <Rd>        The destination register. If S is specified and <Rd> is the PC, see [SUBS PC, LR and related instructions \(T32\) on page F7-3066](#) or [SUBS PC, LR and related instructions \(A32\) on page F7-3068](#). If omitted, <Rd> is SP.
- In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode details of operations on the AArch32 general-purpose registers and the PC on page E1-2296](#).
- <Rm>        The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.
- <shift>     The shift to apply to the value read from <Rm>. If omitted, no shift is applied. [Shifts applied to a register on page F2-2419](#) describes the shifts and how they are encoded.
- In the T32 instruction set, if <Rd> is SP or omitted, <shift> is only permitted to be omitted, LSL #1, LSL #2, or LSL #3.

The pre-UAL syntax SUB<c>S is equivalent to SUBS<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, nzcvc) = AddWithCarry(SP, NOT(shifted), '1');
    if d == 15 then // Can only occur for ARM encoding
        ALUWritePC(result); // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.<N,Z,C,V> = nzcvc;
```

### F7.1.240 SUBS PC, LR and related instructions

These instructions are for system level use only. See *SUBS PC, LR and related instructions (T32)* on page F7-3066 and *SUBS PC, LR and related instructions (A32)* on page F7-3068.

### F7.1.241 SVC (previously SWI)

Supervisor Call, previously called Software Interrupt, causes a Supervisor Call exception. For more information, see *Supervisor Call (SVC) exception on page G1-3479*.

Software can use this instruction as a call to an operating system to provide a service.

In the following cases, the Supervisor Call exception generated by the SVC instruction is taken to Hyp mode:

- If the SVC is executed in Hyp mode.
- If *HCR.TGE* is set to 1, and the SVC is executed in Non-secure User mode. For more information, see *Supervisor Call exception, when HCR.TGE is set to 1 on page G1-3452*

In these cases, the *HSR* identifies that the exception entry was caused by a Supervisor Call exception, EC value 0x11, see *Use of the HSR on page G3-3672*. The immediate field in the *HSR*:

- If the SVC is unconditional:
  - For the T32 instruction, is the zero-extended value of the *imm8* field.
  - For the A32 instruction, is the least-significant 16 bits the *imm24* field.
- If the SVC is conditional, is UNKNOWN.

#### Encoding T1 ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

SVC<c> #<imm8>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	1	1	1	1	1	imm8							

```
imm32 = ZeroExtend(imm8, 32);
// imm32 is for assembly/disassembly. SVC handlers in some
// systems interpret imm8 in software, for example to determine the required service.
```

#### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

cond				1	1	1	1	imm24																							

```
imm32 = ZeroExtend(imm24, 32);
// imm32 is for assembly/disassembly. SVC handlers in some
// systems interpret imm24 in software, for example to determine the required service.
```

## Assembler syntax

SVC{<c>}{<q>} {#}<imm>

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2415.

<imm> Specifies an immediate constant, 8-bit in T32 instructions, or 24-bit in A32 instructions.

The pre-UAL syntax SWI<c> is equivalent to SVC<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.CallSupervisor(imm32<15:0>);
```

## F7.1.242 SXTAB

Signed Extend and Add Byte extracts an 8-bit value from a register, sign-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

### Encoding T1 ARMv6T2, ARMv7

    R[d] = SignExtend(rotated<15:0>, 32);
```

## F7.1.248 TBB, TBH

Table Branch Byte causes a PC-relative forward branch using a table of single byte offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value of the byte returned from the table.

Table Branch Halfword causes a PC-relative forward branch using a table of single halfword offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value of the halfword returned from the table.

### Encoding T1 ARMv6T2, ARMv7

TBB<c> [<Rn>, <Rm>] Outside or last in IT block

TBH<c> [<Rn>, <Rm>, LSL #1] Outside or last in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	0	1	1	0	1	Rn				(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	0	0	H	Rm			

```
n = UInt(Rn); m = UInt(Rm); is_tbh = (H == '1');
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

TBB{<c>}{<q>} [<Rn>, <Rm>]

TBH{<c>}{<q>} [<Rn>, <Rm>, LSL #1]

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2415.

<Rn> The base register. This contains the address of the table of branch lengths. The PC can be used. If it is, the table immediately follows this instruction.

<Rm> The index register.

For TBB, this contains an integer pointing to a single byte in the table. The offset in the table is the value of the index.

For TBH, this contains an integer pointing to a halfword in the table. The offset in the table is twice the value of the index.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); NullCheckIfThumbEE(n);
    if is_tbb then
        halfwords = UInt(MemU[R[n]+LSL(R[m],1), 2]);
    else
        halfwords = UInt(MemU[R[n]+R[m], 1]);
    BranchWritePC(PC + 2*halfwords);
```

### F7.1.249 TEQ (immediate)

Test Equivalence (immediate) performs a bitwise exclusive OR operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

#### Encoding T1 ARMv6T2, ARMv7

TEQ<c> <Rn>, #<const>

```
n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

TEQ{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rn> The first operand register.
- <Rm> The register that is shifted and used as the second operand.
- <type> The type of shift to apply to the value read from <Rm>. It must be one of:
- |     |   |
|-----|---|
| ASR | Arithmetic shift right, encoded as type = 0b10. |
| LSL | Logical shift left, encoded as type = 0b00.     |
| LSR | Logical shift right, encoded as type = 0b01.    |
| ROR | Rotate right, encoded as type = 0b11.           |
- <Rs> The register whose bottom byte contains the amount to shift by.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] EOR shifted;
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    // APSR.V unchanged
```

### F7.1.252 TST (immediate)

Test (immediate) performs a bitwise AND operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

#### Encoding T1 ARMv6T2, ARMv7

TST<c> <Rn>, #<const>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
n = UInt(Rn);
(imm32, carry) = ThumbExpandImm_C(i:imm3:imm8, APSR.C);
if n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

#### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

TST<c> <Rn>, #<const>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	1	1	0	0	0	1	Rn				(0)	(0)	(0)	(0)	imm12													

```
n = UInt(Rn);
(imm32, carry) = ARMEExpandImm_C(imm12, APSR.C);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

TST{<c>}{<q>} <Rn>, #<const>

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2415.

<Rn> The operand register. The PC can be used in A32 instructions.

<const> The immediate value to be tested against the value obtained from <Rn>. See *Modified immediate constants in T32 instructions* on page F3-2444 or *Modified immediate constants in A32 instructions* on page F4-2472 for the range of values.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND imm32;
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    // APSR.V unchanged
```

### F7.1.253 TST (register)

Test (register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

#### Encoding T1 ARMv4T, ARMv5T\*, ARMv6\*, ARMv7

TST<c> <Rn>, <Rm>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	0	1	0	0	0	Rm				Rn	

n = UInt(Rn); m = UInt(Rm);  
 (shift\_t, shift\_n) = (SRTYPE\_LSL, 0);

#### Encoding T2 ARMv6T2, ARMv7

TST<c>.W <Rn>, <Rm>{, <shift>}

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

n = UInt(Rn); m = UInt(Rm);  
 (shift\_t, shift\_n) = DecodeImmShift(type, imm3:imm2);  
 if n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

#### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

TST<c> <Rn>, <Rm>{, <shift>}

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond	0	0	0	1	0	0	0	1	Rn							(0)	(0)	(0)	(0)	imm5	type	0								Rm	

n = UInt(Rn); m = UInt(Rm);  
 (shift\_t, shift\_n) = DecodeImmShift(type, imm5);

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

TST{<c>}{<q>} <Rn>, <Rm> {, <shift>}

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rn> The first operand register. The PC can be used in A32 instructions.
- <Rm> The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.
- <shift> The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. [Shifts applied to a register on page F2-2419](#) describes the shifts and how they are encoded.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] AND shifted;
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    // APSR.V unchanged
```

### F7.1.254 TST (register-shifted register)

Test (register-shifted register) performs a bitwise AND operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

#### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

TST<c> <Rn>, <Rm>, <type> <Rs>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			0	0	0	1	0	0	0	1	Rn				(0)	(0)	(0)	(0)	Rs		0	type		1	Rm						

```
n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

TST{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rn> The first operand register.
- <Rm> The register that is shifted and used as the second operand.
- <type> The type of shift to apply to the value read from <Rm>. It must be one of:
- |     |   |
|-----|---|
| ASR | Arithmetic shift right, encoded as type = 0b10. |
| LSL | Logical shift left, encoded as type = 0b00.     |
| LSR | Logical shift right, encoded as type = 0b01.    |
| ROR | Rotate right, encoded as type = 0b11.           |
- <Rs> The register whose bottom byte contains the amount to shift by.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] AND shifted;
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    // APSR.V unchanged
```

## F7.1.255 UADD8

Unsigned Add 8 performs four unsigned 8-bit integer additions, and writes the results to the destination register. It sets the APSR.GE bits according to the results of the additions.

### Encoding T1 ARMv6T2, ARMv7

UADD8<c> <Rd>, <Rn>, <Rm>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);  
 if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

UADD16{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2415.

<Rd> The destination register.

<Rn> The first operand register.

<Rm> The second operand register.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = UInt(R[n]<15:0>) + UInt(R[m]<15:0>);
    sum2 = UInt(R[n]<31:16>) + UInt(R[m]<31:16>);
    R[d]<15:0> = sum1<15:0>;
    R[d]<31:16> = sum2<15:0>;
    APSR.GE<1:0> = if sum1 >= 0x10000 then '11' else '00';
    APSR.GE<3:2> = if sum2 >= 0x10000 then '11' else '00';
```

## F7.1.257 UASX

Unsigned Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer addition and one unsigned 16-bit subtraction, and writes the results to the destination register. It sets the APSR.GE bits according to the results.

### Encoding T1 ARMv6T2, ARMv7

UASX<c> <Rd>, <Rn>, <Rm>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	0	1	0	1	0	Rn			1	1	1	1	Rd			0	1	0	0	Rm					

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);  
 if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

### Encoding A1 ARMv6\*, ARMv7

UASX<c> <Rd>, <Rn>, <Rm>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	1	1	0	0	1	0	1	Rn			Rd			(1)	(1)	(1)	(1)	0	0	1	1	Rm							

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);  
 if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

UASX{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<Rn> The first operand register.

<Rm> The second operand register.

The pre-UAL syntax UADDSUBX<c> is equivalent to UASX<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff = UInt(R[n]<15:0>) - UInt(R[m]<31:16>);
    sum = UInt(R[n]<31:16>) + UInt(R[m]<15:0>);
    R[d]<15:0> = diff<15:0>;
    R[d]<31:16> = sum<15:0>;
    APSR.GE<1:0> = if diff >= 0 then '11' else '00';
    APSR.GE<3:2> = if sum >= 0x10000 then '11' else '00';
```

## F7.1.258 UBFX

Unsigned Bit Field Extract extracts any number of adjacent bits at any position from a register, zero-extends them to 32 bits, and writes the result to the destination register.

### Encoding T1 ARMv6T2, ARMv7

UBFX<<> <Rd>, <Rn>, #<lsb>, #<width>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	(0)	1	1	1	1	0	0	Rn				0	imm3			Rd			imm2(0)			widthm1					

```
d = UInt(Rd); n = UInt(Rn);
lsbit = UInt(imm3:imm2); widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

### Encoding A1 ARMv6T2, ARMv7

UBFX<<> <Rd>, <Rn>, #<lsb>, #<width>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	1	1	1	1	1	1	widthm1				Rd				lsb				1 0 1			Rn							

```
d = UInt(Rd); n = UInt(Rn);
lsbit = UInt(lsb); widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [UBFX on page AppxA-4723](#).

## Assembler syntax

UBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register.
- <Rn> The first operand register.
- <lsb> Is the bit number of the least significant bit in the field, in the range 0-31. This determines the required value of `lsbit`.
- <width> Is the width of the field, in the range 1 to 32-<lsb>. The required value of `widthminus1` is <width>-1.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsbit + widthminus1;
    if msbit <= 31 then
        R[d] = ZeroExtend(R[n]<msbit:lsbit>, 32);
    else
        UNPREDICTABLE;
```

## F7.1.259 UDF

Permanently Undefined generates an Undefined Instruction exception.

The encodings for UDF used in this section are defined as permanently UNDEFINED in the ARMv8-A architecture. However:

- With the T32 instruction set, ARM deprecates using the UDF instruction in an IT block.
- In the A32 instruction set, UDF is not conditional.

### Encoding T1 ARMv4T, ARMv5T\*, ARMv6, ARMv7

UDF<C> #<imm8>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	1	1	1	1	0	imm8							

imm32 = ZeroExtend(imm8, 32);

// imm32 is for assembly and disassembly only, and is ignored by hardware.

### Encoding T2 ARMv6T2, ARMv7

UDF<C>.W #<imm16>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	1	1	1	1	1	1	1	1	1	1	imm4	1	0	1	0	imm12										

imm32 = ZeroExtend(imm4:imm12, 32);

// imm32 is for assembly and disassembly only, and is ignored by hardware.

### Encoding A1 ARMv4T, ARMv5T\*, ARMv6, ARMv7

UDF<C> #<imm16>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	0	1	1	1	1	1	1	1	imm12						1	1	1	1	imm4									

imm32 = ZeroExtend(imm12:imm4, 32);

// imm32 is for assembly and disassembly only, and is ignored by hardware.

## Assembler syntax

UDF{<c>}{<q>} {#}<imm>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

In the A32 instruction set, <c> must be AL or omitted.

In the T32 instruction set, ARM deprecates using any <c> value other than AL.

<imm> Specifies an immediate constant, that is 8-bit in encoding T1, and 16-bit in encodings T2 and A1.  
The PE ignores the value of this constant.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    UNDEFINED;
```

## F7.1.260 UDIV

Unsigned Divide divides a 32-bit unsigned integer register value by a 32-bit unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.

See [Divide instructions on page F1-2390](#) for more information about this instruction.

**Encoding T1** ARMv7-R, ARMv7VE, otherwise OPTIONAL in ARMv7-A

UDIV<c> <Rd>, <Rn>, <Rm>

```

d = UInt(Rd); n = UInt(Rn); saturate_to = UInt(sat_imm);
(shift_t, shift_n) = DecodeImmShift(sh:'0', imm5);
if d == 15 || n == 15 then UNPREDICTABLE;
    
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

USAT{<c>}{<q>} <Rd>, #<imm>, <Rn> {, <shift>}

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <Rd> The destination register.
- <imm> The bit position for saturation, in the range 0 to 31. This is encoded directly in the sat\_imm field of the instruction, meaning sat\_imm takes the value of <imm>.
- <Rn> The register that contains the value to be saturated.
- <shift> The optional shift, encoded in the sh bit and the immsh field, where immsh is:
- imm3:imm2 for encoding T1.
  - imm5 for encoding A1.
- <shift> must be one of:
- omitted** No shift. Encoded as sh = 0, immsh = 0b00000.
- LSL #<n> Left shift by <n> bits, with <n> in the range 1-31.  
Encoded as sh = 0, immsh = <n>.
- ASR #<n> Arithmetic right shift by <n> bits, with <n> in the range 1-31.  
Encoded as sh = 1, immsh = <n>.
- ASR #32 Arithmetic right shift by 32 bits, permitted only for encoding A1.  
Encoded as sh = 1, immsh = 0b00000.

### Note

An assembler can permit ASR #0 or LSL #0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand = Shift(R[n], shift_t, shift_n, APSR.C); // APSR.C ignored
    (result, sat) = UnsignedSatQ(SInt(operand), saturate_to);
    R[d] = ZeroExtend(result, 32);
    if sat then
        APSR.Q = '1';
```

## F7.1.279 USAT16

Unsigned Saturate 16 saturates two signed 16-bit values to a selected unsigned range.

The Q flag is set if the operation saturates.

**F7.1.289 WFE**

Wait For Event is a hint instruction that permits the PE to enter a low-power state until one of a number of events occurs, including events signaled by executing the SEV instruction on any PE in the multiprocessor system. For more information, see [Wait For Event and Send Event](#) on page G1-3460.

In an implementation that includes EL2, if HCR.TWE is set to 1, execution of a WFE instruction in a Non-secure mode other than Hyp mode generates a Hyp Trap exception if, ignoring the value of the HCR.TWE bit, conditions permit the suspension of execution by the PE. For more information see [Trapping use of the WFI and WFE instructions](#) on page G1-3511.

        elsif HaveEL(EL3) && !ELUsingAArch32(EL3) && SCR_EL3.TWE == '1' then
            AArch64.WFxTrap(EL3, TRUE);
        else
            WaitForEvent();
```

## F7.1.290 WFI

Wait For Interrupt is a hint instruction that permits the PE to enter a low-power state until one of a number of asynchronous events occurs. For more information, see [Wait For Interrupt](#) on page G1-3463.

In an implementation that includes EL2, if HCR.TWI is set to 1, execution of a WFI instruction in a Non-secure mode other than Hyp mode generates a Hyp Trap exception if, ignoring the value of the HCR.TWI bit, conditions permit the suspension of execution by the PE. For more information see [Trapping use of the WFI and WFE instructions](#) on page G1-3511.

    EncodingSpecificOperations();
    if !InterruptPending() then
        if PSTATE.EL == EL0 && SCTLR.nTWI == '0' then
            AArch32.WFxTrap(EL1, FALSE);
        elsif HaveEL(EL2) && !IsSecure() && PSTATE.EL != EL2 && HCR.TWI == '1' then
            AArch32.WFxTrap(EL2, FALSE);
        elsif HaveEL(EL3) && !ELUsingAArch32(EL3) && SCR_EL3.TWI == '1' then
            AArch64.WFxTrap(EL3, FALSE);
        else
            WaitForInterrupt();
```

### F7.1.291 YIELD

YIELD is a hint instruction. Software with a multithreading capability can use a YIELD instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction see [The Yield instruction on page F1-2395](#).

cond				0	0	1	1	0	0	1	0	0	0	0	0	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	0	0	0	0	0	0	1

// No additional decoding required

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

YIELD{<c>}{<q>}

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    Hint_Yield();
```

## F7.2 General restrictions on system instructions

This section describes some restrictions that apply to a number of System instructions. The descriptions of the individual instructions refer to the following subsections when they apply:

- [Restrictions on exception return instructions](#)
- [Restrictions on updates to the CPSR.M field.](#)

### F7.2.1 Restrictions on exception return instructions

A System instruction that is an exception return instruction is UNPREDICTABLE if:

- It is executed in User mode.
- For an exception return instruction other than RFE, it is executed in System mode.
- It is executed in ThumbEE state.
- It attempts to return to Hyp mode and ThumbEE state.
- The [SPSR](#) value it restores to the [CPSR](#) is not permitted because of the restrictions described in [Restrictions on updates to the CPSR.M field.](#)

———— **Note** —————

An exception return instruction that is executed in Hyp mode can set [CPSR.M](#) to a value other than '11010', the value for Hyp mode. However, this does not apply to the following exception return instructions, because the instructions are UNDEFINED in Hyp mode:

- LDM (exception return).
- SUBS PC, LR, #<const> with a nonzero constant.

### F7.2.2 Restrictions on updates to the CPSR.M field

A System instruction that updates the [CPSR.M](#) field is UNPREDICTABLE if it attempts to change to a mode that is not accessible from the context in which the instruction is executed. This means that a System instruction is UNPREDICTABLE if it:

- Attempts to change [CPSR.M](#) to a value that does not correspond to a PE mode. [Table G1-2 on page G1-3412](#) shows the values of M that correspond to a PE mode.
- Is executed in Non-secure state and attempts to set [CPSR.M](#) to '10110', the value for Monitor mode.
- Attempts to set [CPSR.M](#) to '11010', the value for Hyp mode, when any of the following applies:
  - It is executed in a Non-secure mode other than Hyp mode.
  - It is executed in a Secure mode other than Monitor mode.
  - It is executed in Monitor mode when [SCR.NS](#) is set to 0.
  - It is executed in Monitor mode and it is not an exception return instruction.
- Is not an exception return instruction, and is executed in Hyp mode, and attempts to set [CPSR.M](#) to a value other than '11010', the value for Hyp mode.

## F7.3 Encoding and use of Banked register transfer instructions

Software executing at EL1 or higher can use the MRS (Banked register) and MSR (Banked register) instructions to transfer values between the general-purpose registers and Special registers. One particular use of these instructions is for a hypervisor to save or restore the register values of a Guest OS. The following sections give more information about these instructions:

- [Register arguments in the Banked register transfer instructions.](#)
- [Usage restrictions on the Banked register transfer instructions on page F7-3030.](#)
- [Encoding the register argument in the Banked register transfer instructions on page F7-3031.](#)
- [Pseudocode support for the Banked register transfer instructions on page F7-3032.](#)

For descriptions of the instructions see [MRS \(Banked register\) on page F7-3048](#) and [MSR \(Banked register\) on page F7-3050](#).

### F7.3.1 Register arguments in the Banked register transfer instructions

Figure F7-1 shows the Banked general-purpose registers and Special registers:

		Associated mode							
		User or System	Hyp	Supervisor	Abort	Undefined	Monitor	IRQ	FIQ
ARM core registers	R8_usr								R8_fiq
	R9_usr								R9_fiq
	R10_usr								R10_fiq
	R11_usr								R11_fiq
	R12_usr								R12_fiq
	SP_usr	SP_hyp	SP_svc	SP_abt	SP_und	SP_mon	SP_irq	SP_fiq	
LR_usr		LR_svc	LR_abt	LR_und	LR_mon	LR_irq	LR_fiq		
Special registers		SPSR_hyp	SPSR_svc	SPSR_abt	SPSR_und	SPSR_mon	SPSR_irq	SPSR_fiq	
		ELR_hyp							

For the ARM core registers, if no other register is shown, the *current mode register* is the `_usr` register. So, for example, the full set of current mode registers, including the registers that are not banked:

- For Hyp mode, is {R0\_usr - R12\_usr, SP\_hyp, LR\_usr, SPSR\_hyp, ELR\_hyp}.
- For Abort mode, is {R0\_usr - R12\_usr, SP\_abt, LR\_abt, SPSR\_abt}.

**Figure F7-1 Banking of general-purpose registers and Special registers**

Figure F7-1 is based on [Figure G1-2 on page G1-3415](#), that shows the complete set of general-purpose registers and Special registers accessible in each mode.

#### Note

- System mode uses the same set of registers as User mode. Neither of these modes can access an **SPSR**, except that System mode can use the MRS (Banked register) and MSR (Banked register) instructions to access some **SPSRs**, as described in [Usage restrictions on the Banked register transfer instructions on page F7-3030](#).
- General-purpose registers R0-R7, that are not Banked, cannot be accessed using the MRS (Banked register) and MSR (Banked register) instructions.

Software using an MRS (Banked register) or MSR (Banked register) instruction specifies one of these registers using a name shown in [Figure F7-1 on page F7-3029](#), or an alternative name for SP or LR. These registers can be grouped as follows:

<b>R8-R12</b>	Each of these registers has two Banked copies, <code>_usr</code> and <code>_fiq</code> , for example <code>R8_usr</code> and <code>R8_fiq</code> .
<b>SP</b>	There is a Banked copy of SP for every mode except System mode. For example, <code>SP_svc</code> is the SP for Supervisor mode.
<b>LR</b>	There is a Banked copy of LR for every mode except System mode and Hyp mode. For example, <code>LR_svc</code> is the SP for Supervisor mode.
<b>SPSR</b>	There is a Banked copy of <a href="#">SPSR</a> for every mode except System mode and User mode.
<b>ELR_hyp</b>	Except for the operations provided by MRS (Banked register) and MSR (Banked register), <a href="#">ELR_hyp</a> is accessible only from Hyp mode. It is not Banked.

### F7.3.2 Usage restrictions on the Banked register transfer instructions

When software uses an MRS (Banked register) or MSR (Banked register) instruction, the current mode determines the permitted values of the register argument. This determination depends on the rules that an MRS (Banked register) or MSR (Banked register) instruction cannot access:

- A register that is not accessible from the current privilege level and security state. This means that, for example:
  - Non-secure software executing at EL1 or EL2 cannot access any Monitor mode registers.
  - Non-secure software executing at EL1 cannot access any Hyp mode registers.
  - except in Monitor mode, Secure software cannot access any Hyp mode registers.
- A register that can be accessed, from the current mode, using a different instruction.

This means that, for each mode, the registers that cannot be accessed are as follows:

**Hyp mode** The current mode registers `R8_usr-R12_usr`, `SP_hyp`, `LR_usr`, and `SPSR_hyp`.  
The Monitor mode registers `SP_mon`, `LR_mon`, and `SPSR_mon`.

**Monitor mode** The current mode registers `R8_usr-R12_usr`, `SP_mon`, `LR_mon`, and `SPSR_mon`.

**FIQ mode** The current mode registers `R8_fiq-R12_fiq`, `SP_fiq`, `LR_fiq`, and `SPSR_fiq`.  
The Hyp mode registers `SP_hyp`, `SPSR_hyp`, and [ELR\\_hyp](#).  
In Non-secure state, the Monitor mode registers `SP_mon`, `LR_mon`, and `SPSR_mon`.

**System mode** The current mode registers `R8_usr-R12_usr`, `SP_usr`, and `LR_usr`.  
The Hyp mode registers `SP_hyp`, `SPSR_hyp`, and [ELR\\_hyp](#).  
In Non-secure state, the Monitor mode registers `SP_mon`, `LR_mon`, and `SPSR_mon`.

#### Supervisor mode, Abort mode, Undefined mode, and IRQ mode

The current mode registers `R8_usr-R12_usr`, `SP_<current_mode>`, `LR_<current_mode>`, and `SPSR_<current_mode>`.

The Hyp mode registers `SP_hyp`, `SPSR_hyp`, and [ELR\\_hyp](#).

In Non-secure state, the Monitor mode registers `SP_mon`, `LR_mon`, and `SPSR_mon`.

**User mode** MRS (Banked register) and MSR (Banked register) instructions are always UNPREDICTABLE.

In Debug state, the behavior of these instructions is identical to their behavior in Non-debug state.

If software attempts to use an MRS (Banked register) or MSR (Banked register) instruction to access a register from a state from which this section states that the register cannot be accessed, the MRS or MSR instruction is UNPREDICTABLE. For more information, see:

- [Encoding the register argument in the Banked register transfer instructions.](#)
- [Pseudocode support for the Banked register transfer instructions on page F7-3032.](#)
- [MRS \(Banked register\) on page F7-3048.](#)
- [MSR \(Banked register\) on page F7-3050.](#)

———— **Note** —————

UNPREDICTABLE behavior must not give access to registers that are associated with a mode that cannot be entered, from the current mode, using a CPS or MSR instruction.

### F7.3.3 Encoding the register argument in the Banked register transfer instructions

The MRS (Banked register) and MSR (Banked register) instructions include a 5-bit field, SYSm, and an R bit, that together encode the register argument for the instruction.

When the R bit is set to 0, the argument is a register other than a Banked copy of the SPSR, and [Table F7-3](#) shows how the SYSm field defines the required register argument.

**Table F7-3 Banked register encodings when R==0**

	<b>SYSm&lt;4:3&gt;</b>			
<b>SYSm&lt;2:0&gt;</b>	0b00	0b01	0b10	0b11
0b000	R8_usr	R8_fiq	LR_irq	UNPREDICTABLE
0b001	R9_usr	R9_fiq	SP_irq	UNPREDICTABLE
0b010	R10_usr	R10_fiq	LR_svc	UNPREDICTABLE
0b011	R11_usr	R11_fiq	SP_svc	UNPREDICTABLE
0b100	R12_usr	R12_fiq	LR_abt	LR_mon
0b101	SP_usr	SP_fiq	SP_abt	SP_mon
0b110	LR_usr	LR_fiq	LR_und	<a href="#">ELR_hyp</a>
0b111	UNPREDICTABLE	UNPREDICTABLE	SP_und	SP_hyp

When the R bit is set to 1, the argument is a Banked copy of the [SPSR](#), and [Table F7-4](#) shows how the SYSm field defines the required register argument.

**Table F7-4 Banked register encodings when R==1**

SYSm<2:0>	SYSm<4:3>			
	0b00	0b01	0b10	0b11
0b000	UNPREDICTABLE	UNPREDICTABLE	SPSR_irq	UNPREDICTABLE
0b001	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE
0b010	UNPREDICTABLE	UNPREDICTABLE	SPSR_svc	UNPREDICTABLE
0b011	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE
0b100	UNPREDICTABLE	UNPREDICTABLE	SPSR_abt	SPSR_mon
0b101	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE
0b110	UNPREDICTABLE	SPSR_fiq	SPSR_und	SPSR_hyp
0b111	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE

#### F7.3.4 Pseudocode support for the Banked register transfer instructions

The pseudocode functions `BankedRegisterAccessValid()` and `SPSRAccessValid()` check the validity of MRS (Banked register) and MSR (Banked register) accesses. That is, they filter the accesses that are UNPREDICTABLE either because:

- They attempt to access a register that [Usage restrictions on the Banked register transfer instructions on page F7-3030](#) shows is not accessible.
- They use an SYSm<4:0> encoding that [Encoding the register argument in the Banked register transfer instructions on page F7-3031](#) shows as UNPREDICTABLE.

`BankedRegisterAccessValid()` applies to accesses to the banked general-purpose registers, or to [ELR\\_hyp](#), and `SPSRAccessValid()` applies to accesses to the [SPSRs](#).

## F7.4 Alphabetical list of system instructions

This section lists every instruction that behaves differently when executed at EL1 or higher, or that is only available at EL1 or higher. For more information see [Exception levels on page G1-3401](#).

## F7.4.1 CPS (T32)

Change PE State changes one or more of the **CPSR**.{A, I, F} interrupt mask bits and the **CPSR.M** mode field, without changing the other **CPSR** bits.

CPS is treated as NOP if executed in User mode.

CPS is UNPREDICTABLE if it is attempting to change to a mode that is not permitted in the context in which it is executed, see [Restrictions on updates to the CPSR.M field on page F7-3028](#).

### Encoding T1 ARMv6\*, ARMv7

CPS<effect> <iflags> Not permitted in IT block.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	0	1	1	0	0	1	1	im	(0)	A	I	F

```
if A:I:F == '000' then UNPREDICTABLE;
enable = (im == '0'); disable = (im == '1'); changemode = FALSE;
affectA = (A == '1'); affectI = (I == '1'); affectF = (F == '1');
if InITBlock() then UNPREDICTABLE;
```

### Encoding T2 ARMv6T2, ARMv7

CPS<effect>.W <iflags>{, #<mode>} Not permitted in IT block.

CPS #<mode> Not permitted in IT block.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	0	(1)	(1)	(1)	(1)	1	0	(0)	0	(0)	imod	M	A	I	F	mode					

```
if imod == '00' && M == '0' then SEE "Hint instructions";
if mode != '0000' && M == '0' then UNPREDICTABLE;
if (imod<1> == '1' && A:I:F == '000') || (imod<1> == '0' && A:I:F != '000') then UNPREDICTABLE;
enable = (imod == '10'); disable = (imod == '11'); changemode = (M == '1');
affectA = (A == '1'); affectI = (I == '1'); affectF = (F == '1');
if imod == '01' || InITBlock() then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [CPS \(T32\) on page AppxA-4754](#).

### Hint instructions

In encoding T2, if the **imod** field is '00' and the **M** bit is '0', a hint instruction is encoded. To determine which hint instruction, see [Change Processor State, and hints on page F3-2448](#).

## Assembler syntax

```
CPS<effect>{<q>} <iflags> {, #<mode>}
CPS{<q>} #<mode>
```

where:

- <effect> The effect required on the A, I, and F bits in the **CPSR**. This is one of:
- IE Interrupt Enable. This sets the specified bits to 0.
  - ID Interrupt Disable. This sets the specified bits to 1.
- If <effect> is specified, the bits to be affected are specified by <iflags>. The mode can optionally be changed by specifying a mode number as <mode>.
- If <effect> is not specified, then:
- <iflags> is not specified and interrupt settings are not changed.
  - <mode> specifies the new mode number.
- <q> See [Standard assembler syntax fields on page F2-2415](#). A CPS instruction must be unconditional.
- <iflags> Is a sequence of one or more of the following, specifying which interrupt mask bits are affected:
- a Sets the A bit in the instruction, causing the specified effect on **CPSR.A**, the asynchronous abort bit.
  - i Sets the I bit in the instruction, causing the specified effect on **CPSR.I**, the IRQ interrupt bit.
  - f Sets the F bit in the instruction, causing the specified effect on **CPSR.F**, the FIQ interrupt bit.
- <mode> The number of the mode to change to. If this option is omitted, no mode change occurs.

## Operation

```
EncodingSpecificOperations();
if CurrentModeIsNotUser() then
  cpsr_val = CPSR;
  if enable then
    if affectA then cpsr_val<8> = '0';
    if affectI then cpsr_val<7> = '0';
    if affectF then cpsr_val<6> = '0';
  if disable then
    if affectA then cpsr_val<8> = '1';
    if affectI then cpsr_val<7> = '1';
    if affectF then cpsr_val<6> = '1';
  if changemode then
    cpsr_val<4:0> = mode;
  // Attempts to change to an illegal mode, or Hyp mode with CPSR.<J,T> = '11'
  // will invoke the Illegal Execution State mechanism
  CPSRWriteByInstr(cpsr_val, '1111', FALSE);
```

## F7.4.2 CPS (A32)

Change PE State changes one or more of the **CPSR**.{A, I, F} interrupt mask bits and the **CPSR.M** mode field, without changing the other **CPSR** bits.

CPS is treated as NOP if executed in User mode.

CPS is UNPREDICTABLE if it is attempting to change to a mode that is not permitted in the context in which it is executed, see *Restrictions on updates to the CPSR.M field* on page F7-3028.

### Encoding A1 ARMv6\*, ARMv7

```

if mode != '00000' && M == '0' then UNPREDICTABLE;
if (imod<1> == '1' && A:I:F == '000') || (imod<1> == '0' && A:I:F != '000') then UNPREDICTABLE;
enable = (imod == '10'); disable = (imod == '11'); changemode = (M == '1');
affectA = (A == '1'); affectI = (I == '1'); affectF = (F == '1');
if (imod == '00' && M == '0') || imod == '01' then UNPREDICTABLE;
    
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *CPS (A32)* on page AppxA-4754.

## Assembler syntax

```
CPS<effect>{<q>} <iflags> {, #<mode>}
CPS{<q>} #<mode>
```

where:

- <effect> The effect required on the A, I, and F bits in the **CPSR**. This is one of:
- IE Interrupt Enable. This sets the specified bits to 0.
  - ID Interrupt Disable. This sets the specified bits to 1.
- If <effect> is specified, the bits to be affected are specified by <iflags>. The mode can optionally be changed by specifying a mode number as <mode>.
- If <effect> is not specified, then:
- <iflags> is not specified and interrupt settings are not changed.
  - <mode> specifies the new mode number.
- <q> See [Standard assembler syntax fields on page F2-2415](#). A CPS instruction must be unconditional.
- <iflags> Is a sequence of one or more of the following, specifying which interrupt mask bits are affected:
- a Sets the A bit in the instruction, causing the specified effect on **CPSR.A**, the asynchronous abort bit.
  - i Sets the I bit in the instruction, causing the specified effect on **CPSR.I**, the IRQ interrupt bit.
  - f Sets the F bit in the instruction, causing the specified effect on **CPSR.F**, the FIQ interrupt bit.
- <mode> The number of the mode to change to. If this option is omitted, no mode change occurs.

## Operation

```
EncodingSpecificOperations();
if CurrentModeIsNotUser() then
  cpsr_val = CPSR;
  if enable then
    if affectA then cpsr_val<8> = '0';
    if affectI then cpsr_val<7> = '0';
    if affectF then cpsr_val<6> = '0';
  if disable then
    if affectA then cpsr_val<8> = '1';
    if affectI then cpsr_val<7> = '1';
    if affectF then cpsr_val<6> = '1';
  if changemode then
    cpsr_val<4:0> = mode;
  // Attempts to change to an illegal mode, or Hyp mode with CPSR.<J,T> = '11'
  // will invoke the Illegal Execution State mechanism
  CPSRWriteByInstr(cpsr_val, '1111', FALSE);
```

### F7.4.3 ERET

When executed in Hyp mode, Exception Return loads the PC from [ELR\\_hyp](#) and loads the [CPSR](#) from [SPSR\\_hyp](#).

When executed in a Secure or Non-secure EL1 mode, ERET behaves as:

- MOV<sub>S</sub> PC, LR in the A32 instruction set, see [SUBS PC, LR and related instructions \(A32\) on page F7-3068](#).
- The equivalent SUBS PC, LR, #0 in the T32 instruction set, see [SUBS PC, LR and related instructions \(T32\) on page F7-3066](#).

In Debug state, ERET is decoded as DRPS.

ERET is CONstrained UNPREDICTABLE in the cases described in [Restrictions on exception return instructions on page F7-3028](#).

———— **Note** —————

In an implementation that includes EL2:

- The T1 encoding of ERET is not a new encoding but, is the preferred synonym of SUBS PC, LR, #0 in the T32 instruction set. See [SUBS PC, LR and related instructions \(T32\) on page F7-3066](#) for more information.
- Because ERET is the preferred encoding, when decoding T32 instructions, a disassembler reports an ERET where the original assembler code used SUBS PC, LR, #0.

**Encoding T1** ARMv6T2, ARMv7VE, see syntax rows.

SUBS PC, LR, #0 ARMv6T2, ARMv7

For information about the CONstrained UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

ERET{<c>}{<q>}

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2415.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentModeIsUserOrSystem() || CurrentInstrSet() == InstrSet_T32EE then
        UNPREDICTABLE; // UNDEFINED or NOP
    else
        new_pc_value = if CurrentModeIsHyp() then ELR_hyp else R[14];
        AArch32.ExceptionReturn(new_pc_value, SPSR[]);
```

## F7.4.4 HVC

Hypervisor Call causes a Hypervisor Call exception. For more information see [Hypervisor Call \(HVC\) exception on page G1-3481](#). Non-secure software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is:

- UNDEFINED in Secure state, and in User mode in Non-secure state.
- When `SCR.HCE` is set to 0, UNDEFINED in Non-secure EL1 modes and CONSTRAINED UNPREDICTABLE in Hyp mode.

On executing an HVC instruction, the `HSR` reports the exception as a Hypervisor Call exception, using the EC value `0x12`, and captures the value of the immediate argument, see [Use of the HSR on page G3-3672](#).

### Encoding T1 ARMv7VE

imm16 = imm12:imm4;
// imm16 is for assembly/disassembly. It is reported in the HSR but otherwise is ignored by
// hardware. An HVC handler might interpret imm16, for example to determine the required service.
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

HVC{<q>} {#}<imm16>

where:

<q> See *Standard assembler syntax fields* on page F2-2415. An HVC instruction must be unconditional.

<imm16> Specifies a 16-bit immediate constant.

## Operation

```
EncodingSpecificOperations();
if !HaveEL(EL2) || PSTATE.EL == EL0 || (PSTATE.EL == EL1 && IsSecure()) then
    UNDEFINED;

hvc_enable = if HaveEL(EL3) then SCR_GEN[].HCE else NOT(HCR.HCD);
if hvc_enable == '0' then
    UNDEFINED;
else
    AArch32.CallHypervisor(imm16);
```

## F7.4.5 LDM (exception return)

Load Multiple (exception return) loads multiple registers from consecutive memory locations using an address from a base register. The **SPSR** of the current mode is copied to the **CPSR**. An address adjusted by the size of the data loaded can optionally be written back to the base register.

The registers loaded include the PC. The word loaded for the PC is treated as an address and a branch occurs to that address.

LDM (exception return) is:

- UNDEFINED in Hyp mode.
- UNPREDICTABLE in the cases described in [Restrictions on exception return instructions on page F7-3028](#).

### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

LDM{<amode>}<c> <Rn>{!}, <registers\_with\_pc>^

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		1	0	0	P	U	1	W	1	Rn								register_list													

```
n = UInt(Rn); registers = register_list;
wback = (W == '1'); increment = (U == '1'); wordhigher = (P == U);
if n == 15 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDM \(exception return\) on page AppxA-4755](#).

### Assembler syntax

LDM{<amode>}{<c>}{<q>} <Rn>{!}, <registers\_with\_pc>^

where:

<amode> is one of:

- |    |  |
|----|--|
| DA | Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.                        |
| FA | Full Ascending. For this instruction, a synonym for DA.  |
| DB | Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.           |
| EA | Empty Ascending. For this instruction, a synonym for DA.   |
| IA | Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1. |
| FD | Full Descending. For this instruction, a synonym for IA.   |
| IB | Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.         |
| ED | Empty Descending. For this instruction, a synonym for IB.  |

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rn> The base register. This register can be the SP.

! Causes the instruction to write a modified value back to <Rn>. Encoded as W = 1.  
 If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.

<registers\_with\_pc>

Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must be specified in the register list, and the instruction causes a branch to the address (data) loaded into the PC. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2426.

The pre-UAL syntax LDM<c>{<amode>} is equivalent to LDM{<amode>}<c>.

———— **Note** —————

Instructions with similar syntax but without the PC included in the registers list are described in *LDM (User registers)* on page F7-3044.

**Operation**

```

if ConditionPassed() then
  EncodingSpecificOperations();
  if CurrentModeIsHyp() then
    UNDEFINED;
  elseif CurrentModeIsUserOrSystem() || CurrentInstrSet() == InstrSet_T32EE then
    UNPREDICTABLE; // UNDEFINED or NOP
  else
    length = 4*BitCount(registers) + 4;
    address = if increment then R[n] else R[n]-length;
    if wordhigher then address = address+4;

    for i = 0 to 14
      if registers<i> == '1' then
        R[i] = MemA[address,4]; address = address + 4;
    new_pc_value = MemA[address,4];

    if wback && registers<n> == '0' then R[n] = if increment then R[n]+length else R[n]-length;
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;

    AArch32.ExceptionReturn(new_pc_value, SPSR[]);
  
```

### F7.4.6 LDM (User registers)

In an EL1 mode other than System mode, Load Multiple (User registers) loads multiple User mode registers from consecutive memory locations using an address from a base register. The registers loaded cannot include the PC. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

LDM (user registers) is UNDEFINED in Hyp mode, and UNPREDICTABLE in User and System modes.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

LDM{<amode>}<c> <Rn>, <registers\_without\_pc>^

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond			1	0	0	P	U	1	(0)	1	Rn						0	register_list													

n = UInt(Rn); registers = register\_list; increment = (U == '1'); wordhigher = (P == U);  
 if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [LDM \(User registers\) on page AppxA-4755](#).

## Assembler syntax

LDM{<amode>}{<c>}{<q>} <Rn>, <registers\_without\_pc>^

where:

<amode> is one of:

- DA Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
- FA Full Ascending. For this instruction, a synonym for DA.
- DB Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
- EA Empty Ascending. For this instruction, a synonym for DB.
- IA Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
- FD Full Descending. For this instruction, a synonym for IA.
- IB Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
- ED Empty Descending. For this instruction, a synonym for IB.

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rn> The base register. This register can be the SP.

<registers\_without\_pc>

Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded by the LDM instruction. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must not be in the register list. See also [Encoding of lists of general-purpose registers and the PC on page F2-2426](#).

The pre-UAL syntax LDM<c>{<amode>} is equivalent to LDM{<amode>}<c>.

### ———— Note —————

Instructions with similar syntax but with the PC included in <registers\_without\_pc> are described in [LDM \(exception return\) on page F7-3042](#).

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentModeIsHyp() then UNDEFINED;
    elsif CurrentModeIsUserOrSystem() then UNPREDICTABLE;
    else
        length = 4*BitCount(registers);
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address+4;
        for i = 0 to 14
            if registers<i> == '1' then // Load User mode register
                Rmode[i, M32_User] = MemA[address,4]; address = address + 4;
  
```

### F7.4.7 LDRBT, LDRHT, LDRSBT, LDRSHT, and LDRT

Even when executed at EL1 or higher, loads from memory by these instructions are restricted in the same way as unprivileged loads from memory. The MemA\_unpriv[] and MemU\_unpriv[] pseudocode functions describe this restriction. For more information see [Alignment support on page E2-2341](#).

These instructions are UNPREDICTABLE in Hyp mode.

For descriptions of the instructions see:

- [LDRBT on page F7-2652](#).
- [LDRHT on page F7-2672](#).
- [LDRSBT on page F7-2680](#).
- [LDRSHT on page F7-2688](#).
- [LDRT on page F7-2690](#).

### F7.4.8 MRS

Move to Register from Special register moves the value from the [CPSR](#) or [SPSR](#) of the current mode into a general-purpose register.

An MRS that accesses the [SPSR](#) is UNPREDICTABLE if executed in User mode or System mode.

An MRS that is executed in User mode and accesses the [CPSR](#) returns an UNKNOWN value for the [CPSR](#).{E, A, I, F, M} fields.

———— **Note** —————

[MRS on page F7-2720](#) describes the valid application level uses of the MRS instruction.

#### Encoding T1 ARMv6T2, ARMv7

d = UInt(Rd); read\_spsr = (R == '1');  
 if d == 15 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [MRS on page AppxA-4756](#).

## Assembler syntax

MRS{<c>}{<q>} <Rd>, <spec\_reg>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rd> The destination register.

<spec\_reg> Is one of:

- APSR
- CPSR
- SPSR.

ARM recommends that software uses the APSR form when only the N, Z, C, V, Q, or GE[3:0] bits of the read value are going to be used, see [The Application Program Status Register \(APSR\) on page E1-2297](#).

## Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  if read_spsr then
    if CurrentModeIsUserOrSystem() then
      UNPREDICTABLE;
    else
      R[d] = SPSR[];
  else
    // CPSR is read with execution state bits other than E masked out.
    R[d] = CPSR AND '11111000 11111111 00000011 11011111';
    if !CurrentModeIsNotUser() then
      // If accessed from User mode return UNKNOWN values for M, bits<4:0>,
      // and for the E, A, I, F bits, bits<9:6>
      R[d]<4:0> = bits(5) UNKNOWN;
      R[d]<9:6> = bits(4) UNKNOWN;
```

## F7.4.9 MRS (Banked register)

Move to Register from Banked or Special register moves the value from the Banked general-purpose register or **SPSR** of the specified mode, or the value of **ELR\_hyp**, to a general-purpose register.

MRS (Banked register) is UNPREDICTABLE if executed in User mode.

The effect of using an MRS (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see *Usage restrictions on the Banked register transfer instructions* on page F7-3030.

### Encoding T1 ARMv7VE

          R[d] = ELR_hyp;
      else                                 // Other Banked registers
        bits(5) targetmode;              // (SYSm<4:3> == '10' case)
        targetmode<0> = SYSm<2> OR SYSm<1>;
        targetmode<1> = '1';
        targetmode<2> = SYSm<2> AND NOT SYSm<1>;
        targetmode<3> = SYSm<2> AND SYSm<1>;
        targetmode<4> = '1';
        if mode == targetmode then
          UNPREDICTABLE;
        else
          m = 14 - UInt(SYSm<0>);          // LR when SYSm<0> == 0, otherwise SP
          R[d] = Rmode[m,targetmode];
  
```

### F7.4.10 MSR (Banked register)

Move to Banked or Special register from general-purpose register moves the value of a general-purpose register to the Banked general-purpose register or *SPSR* of the specified mode, or to *ELR\_hyp*.

MSR (Banked register) is UNPREDICTABLE if executed in User mode.

The effect of using an MSR (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see *Usage restrictions on the Banked register transfer instructions* on page F7-3030.

#### Encoding T1 ARMv7VE

MSR<c> <banked\_reg>, <Rn>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

if n == 15 then UNPREDICTABLE;
SYSm = M:M1;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

#### Assembler syntax

MSR{<c>}{<q>} <banked\_reg>, <Rn>

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2415.

<banked\_reg> Is one of:

- <Rm>\_<mode>, encoded with R==0.
- ELR\_hyp, encoded with R==0.
- SPSR\_<mode>, encoded with R==1.

For a full description of the encoding of this field, see *Encoding and use of Banked register transfer instructions* on page F7-3029.

<Rn> Is the general-purpose register to be transferred to <banked\_reg>.

## Operation

```

if ConditionPassed() then
  EncodingSpecificOperations();
  if !CurrentModeIsNotUser() then
    UNPREDICTABLE;
  else
    mode = CPSR.M;
    if write_spsr then
      SPSRaccessValid(SYSm, mode); // Check for UNPREDICTABLE cases
      case SYSm of
        when '01110' SPSR_fiq = R[n];
        when '10000' SPSR_irq = R[n];
        when '10010' SPSR_svc = R[n];
        when '10100' SPSR_abt = R[n];
        when '10110' SPSR_und = R[n];
        when '11100' SPSR_mon = R[n];
        when '11110' SPSR_hyp = R[n];
      else
        BankedRegisterAccessValid(SYSm, mode); // Check for UNPREDICTABLE cases

        if SYSm<4:3> == '00' then // Access the User registers

            Rmode[m,targetmode] = R[n];
          end
        end
      end
    end
  end

```

### F7.4.11 MSR (immediate)

Move immediate value to Special register moves selected bits of an immediate value to the **CPSR** or the **SPSR** of the current mode.

MSR (immediate) is UNPREDICTABLE if it is attempting to update the **CPSR**, and that update would change to a mode that is not permitted in the context in which the instruction is executed, see *Restrictions on updates to the CPSR.M field* on page F7-3028.

An MSR (immediate) executed in User mode:

- Is CONSTRAINED UNPREDICTABLE if it attempts to update the **SPSR**.
- Otherwise, does not update any **CPSR** field that is accessible only at EL1 or higher,

———— **Note** —————

*MSR (immediate)* on page F7-2722 describes the valid application level uses of the MSR (immediate) instruction.

An MSR (immediate) executed in System mode is CONSTRAINED UNPREDICTABLE if it attempts to update the **SPSR**.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

MSR<c> <spec\_reg>, #<const>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	1	1	0	R	1	0	mask				(1)	(1)	(1)	(1)	imm12													

```
if mask == '0000' && R == '0' then SEE "Related encodings";
imm32 = ARMEExpandImm(imm12); write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *MSR (immediate)* on page AppxA-4756.

**Related encodings** See *MSR (immediate)*, and *hints* on page F4-2478.

## Assembler syntax

MSR{<c>}{<q>} <spec\_reg>, #<const>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<spec\_reg> Is one of:

- APSR\_<bits>.
- CPSR\_<fields>.
- SPSR\_<fields>.

ARM recommends the APSR forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see [The Application Program Status Register \(APSR\) on page E1-2297](#).

<const> The immediate value to be transferred to <spec\_reg>. See [Modified immediate constants in A32 instructions on page F4-2472](#) for the range of values.

<bits> Is one of nzcqv, g, or nzcqvq.

In the A and R profiles:

- APSR\_nzcqv is the same as CPSR\_f (mask == '1000').
- APSR\_g is the same as CPSR\_s (mask == '0100').
- APSR\_nzcqvq is the same as CPSR\_fs (mask == '1100').

<fields> Is a sequence of one or more of the following:

- c mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.
- x mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.
- s mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.
- f mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        SPSRWriteByInstr(imm32, mask);
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution State mechanism
        CPSRWriteByInstr(imm32, mask, FALSE); // Does not affect execution state bits other than E
```

## E bit

The **CPSR.E** bit is writable from any mode using an MSR instruction. ARM deprecates using this to change its value. Use the SETEND instruction instead.

## F7.4.12 MSR (register)

Move to Special register from general-purpose register moves the value of a general-purpose register to the **CPSR** or the **SPSR** of the current mode.

MSR (register) is UNPREDICTABLE if it is attempting to update the **CPSR**, and that update would change to a mode that is not permitted in the context in which the instruction is executed, see *Restrictions on updates to the CPSR.M field* on page F7-3028.

An MSR (register) executed in User mode:

- Is UNPREDICTABLE if it attempts to update the **SPSR**.
- Otherwise, does not update any **CPSR** field that is accessible only at EL1 or higher,

———— **Note** —————

*MSR (register)* on page F7-2724 describes the valid application level uses of the MSR (register) instruction.

An MSR (register) executed in System mode is UNPREDICTABLE if it attempts to update the **SPSR**.

### Encoding T1 ARMv6T2, ARMv7

```
n = UInt(Rn); write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;
if n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *MSR (register)* on page AppxA-4756.

## Assembler syntax

MSR{<c>}{<q>} <spec\_reg>, <Rn>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<spec\_reg> Is one of:

- APSR\_<bits>.
- CPSR\_<fields>.
- SPSR\_<fields>.

ARM recommends the APSR forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see [The Application Program Status Register \(APSR\) on page E1-2297](#).

<Rn> Is the general-purpose register to be transferred to <spec\_reg>.

<bits> Is one of nzcvcq, g, or nzcvcqg.

In the A profile:

- APSR\_nzcvcq is the same as CPSR\_f (mask == '1000').
- APSR\_g is the same as CPSR\_s (mask == '0100').
- APSR\_nzcvcqg is the same as CPSR\_fs (mask == '1100').

<fields> Is a sequence of one or more of the following:

- c mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.
- x mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.
- s mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.
- f mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        SPSRWriteByInstr(R[n], mask);
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution State mechanism
        CPSRWriteByInstr(R[n], mask, FALSE); // Does not affect execution state bits other than E
```

## E bit

The [CPSR.E](#) bit is writable from any mode using an MSR instruction. ARM deprecates using this to change its value. Use the SETEND instruction instead.

### F7.4.13 RFE

Return From Exception loads the PC and the CPSR from the word at the specified address and the following word respectively. For information about memory accesses see [Memory accesses on page F2-2422](#).

RFE is:

- UNDEFINED in Hyp mode.
- UNPREDICTABLE in the cases described in [Restrictions on exception return instructions on page F7-3028](#).

———— **Note** ————

As identified in [Restrictions on exception return instructions on page F7-3028](#), RFE differs from other exception return instructions in that it can be executed in System mode.

#### Encoding T1 ARMv6T2, ARMv7

```
n = UInt(Rn);
wback = (W == '1'); inc = (U == '1'); wordhigher = (P == U);
if n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [RFE on page AppxA-4757](#).

## Assembler syntax

RFE{<amode>}{<C>}{<q>} <Rn>{!}

where:

<amode> is one of:

- DA Decrement After. A32 instructions only. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0 in encoding A1.
- DB Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoding T1, or encoding A1 with P = 1, U = 0.
- IA Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoding T2, or encoding A1 with P = 0, U = 1.
- IB Increment Before. A32 instructions only. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1 in encoding A1.

<C>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 RFE instruction must be unconditional.

<Rn> The base register.

! Causes the instruction to write a modified value back to <Rn>. If ! is omitted, the instruction does not change <Rn>.

RFEFA, RFEEA, RFEFD, and RFEED are pseudo-instructions for RFEDA, RFEDB, RFEIA, and RFEIB respectively, referring to their use for popping data from Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentModeIsHyp() then
        UNDEFINED;
    elseif (!CurrentModeIsNotUser() || CurrentInstrSet() == InstrSet_T32EE) then
        UNPREDICTABLE; // UNDEFINED or NOP
    else
        address = if increment then R[n] else R[n]-8;
        if wordhigher then address = address+4;
        if wback then R[n] = if increment then R[n]+8 else R[n]-8;
        new_pc_value = MemA[address,4];
        spsr = MemA[address+4,4];
        AArch32.ExceptionReturn(new_pc_value, spsr);
  
```

### F7.4.14 SMC (previously SMI)

Secure Monitor Call causes a Secure Monitor Call exception. For more information see [Secure Monitor Call \(SMC\) exception on page G1-3480](#).

SMC is available only from software executing at EL1 or higher. It is UNDEFINED in User mode.

If `HCR.TSC` is set to 1, execution of an SMC instruction in a Non-secure EL1 mode generates a Hyp Trap exception, regardless of the value of `SCR.SCD`. For more information see [Trapping use of the SMC instruction on page G1-3510](#).

Otherwise, when `SCR.SCD` is set to 1, the SMC instruction is:

- UNDEFINED in Non-secure state.
- UNPREDICTABLE if executed:
  - When EL3 is using AArch32, in a Secure EL3 mode.
  - When EL3 is using AArch32, in a Secure EL1 mode.

#### Encoding T1 Security Extensions (not in ARMv6K)

SMC<c> #<imm4>

// imm4 is for assembly/disassembly only and is ignored by hardware  
 if InITBlock() && !LastInITBlock() then UNPREDICTABLE;

#### Encoding A1 Security Extensions

SMC<c> #<imm4>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		0	0	0	1	0	1	1	0	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	0	1	1	1	imm4			

// imm4 is for assembly/disassembly only and is ignored by hardware

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

SMC{<c>}{<q>} {#}<imm4>

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2415.

<imm4> Is a 4-bit immediate value. This is ignored by the PE.

The Secure Monitor Call exception handler (Secure Monitor code) can use this value to determine what service is being requested, but ARM does not recommend this.

The pre-UAL syntax SMI<c> is equivalent to SMC<c>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();

    if !HaveEL(EL3) || PSTATE.EL == EL0 then
        UNDEFINED;

    route_to_hyp = HaveEL(EL2) && !IsSecure() && HCR.TSC == '1';

    if route_to_hyp then
        AArch32.SMCTrap();
    elseif SCR_GEN[.SCD] == '1' then
        // SMC disabled
        if IsSecure() then
            // Executes either as a NOP or UNALLOCATED.
            c = ConstrainUnpredictable(Unpredictable_SMD);
            assert c IN {Constraint_NOP, Constraint_UNDEF};
            if c == Constraint_NOP then EndOfInstruction();
        UNDEFINED;
    elseif !ELUsingAArch32(EL3) then
        AArch64.CallSecureMonitor(Zeros(16));
    else
        AArch32.TakeSMCException();
```

### F7.4.15 SRS (T32)

Store Return State stores the LR and SPSR of the current mode to the stack of a specified mode. For information about memory accesses see [Memory accesses on page F2-2422](#).

SRS is:

- UNDEFINED in Hyp mode.
- UNPREDICTABLE if:
  - It is executed in ThumbEE state.
  - It is executed in User or System mode.
  - It attempts to store the Monitor mode SP when in Non-secure state.
  - It attempts to store the Hyp mode SP.

#### Encoding T1 ARMv6T2, ARMv7

if CurrentInstrSet() == InstrSet\_T32EE then UNPREDICTABLE;  
 wback = (W == '1'); increment = TRUE; wordhigher = FALSE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [SRS \(T32\) on page AppxA-4757](#).

## Assembler syntax

SRS{<amode>}{<C>}{<q>} SP{!}, #<mode>

where:

- <amode> is one of:
- DB Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoding T1.
  - IA Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoding T2.
- <C>, <q> See *Standard assembler syntax fields* on page F2-2415.
- ! Causes the instruction to write a modified value back to the base register (encoded as W = 1). If ! is omitted, the instruction does not change the base register (encoded as W = 0).
- <mode> The number of the mode whose Banked SP is used as the base register. For details of PE modes and their numbers see *AArch32 PE mode descriptions* on page G1-3412.

SRSEA is a pseudo-instruction for SRSIA, and SRSFD is a pseudo-instruction for SRSDB, referring to their use for pushing data onto Empty Ascending and Full Descending stacks.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentModeIsHyp() then
        UNDEFINED;
    elseif CurrentModeIsUserOrSystem() then
        UNPREDICTABLE;
    elseif mode == M32_Hyp then // Check for attempt to access Hyp mode SP
        UNPREDICTABLE;
    elseif !IsSecure() && mode == M32_Monitor then
        // In Non-secure state, check for attempts to access Monitor mode.
        // The definition of UNPREDICTABLE does not permit this to be a security hole.
        UNPREDICTABLE;
    base = Rmode[13,mode];
    address = if increment then base else base-8;
    if wordhigher then address = address+4;
    MemA[address,4] = LR;
    MemA[address+4,4] = SPSR[];
    if wback then Rmode[13,mode] = if increment then base+8 else base-8;
  
```

### F7.4.16 SRS (A32)

Store Return State stores the LR and SPSR of the current mode to the stack of a specified mode. For information about memory accesses see [Memory accesses on page F2-2422](#).

SRS is:

- UNDEFINED in Hyp mode.
- UNPREDICTABLE if:
  - It is executed in User or System mode.
  - It attempts to store the Monitor mode SP when in Non-secure state.
  - If it attempts to store the Hyp mode SP.

#### Encoding A1 ARMv6\*, ARMv7

SRS{<amode>} SP{!}, #<mode>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	0	P	U	1	W	0	(1)	(1)	(0)	(1)	(0)	(0)	(0)	(0)	(0)	(1)	(0)	(1)	(0)	(0)	(0)	mode				

wback = (W == '1'); increment = (U == '1'); wordhigher = (P == U);

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [SRS \(A32\) on page AppxA-4758](#).

## Assembler syntax

SRS{<amode>}{<C>}{<q>} SP{!}, #<mode>

where:

<amode>	is one of:
DA	Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
DB	Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
IA	Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
IB	Increment Before. A32 instructions only. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
<C>, <q>	See <i>Standard assembler syntax fields on page F2-2415</i> . In the A32 instruction set, an SRS instruction must be unconditional.
!	Causes the instruction to write a modified value back to the base register (encoded as W = 1). If ! is omitted, the instruction does not change the base register (encoded as W = 0).
<mode>	The number of the mode whose Banked SP is used as the base register. For details of PE modes and their numbers see <i>AArch32 PE mode descriptions on page G1-3412</i> .

SRSFA, SRSEA, SRSFD, and SRSED are pseudo-instructions for SRSIB, SRSIA, SRSDB, and SRSDA respectively, referring to their use for pushing data onto Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentModeIsHyp() then
        UNDEFINED;
    elsif CurrentModeIsUserOrSystem() then
        UNPREDICTABLE;
    elsif mode == M32_Hyp then // Check for attempt to access Hyp mode SP
        UNPREDICTABLE;
    elsif !IsSecure() && mode == M32_Monitor then
        // In Non-secure state, check for attempts to access Monitor mode.
        // The definition of UNPREDICTABLE does not permit this to be a security hole.
        UNPREDICTABLE;
    base = Rmode[13,mode];
    address = if increment then base else base-8;
    if wordhigher then address = address+4;
    MemA[address,4] = LR;
    MemA[address+4,4] = SPSR[];
    if wback then Rmode[13,mode] = if increment then base+8 else base-8;
  
```

### F7.4.17 STM (User registers)

In an EL1 mode other than System mode, Store Multiple (user registers) stores multiple User mode registers to consecutive memory locations using an address from a base register. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

STM (User registers) is UNDEFINED in Hyp mode, and CONSTRAINED UNPREDICTABLE in User or System modes.

**Encoding A1** ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

STM{<amode>}<c> <Rn>, <registers>^

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1	0	0	P	U	1	(0)	0	Rn				register_list															

n = UInt(Rn); registers = register\_list; increment = (U == '1'); wordhigher = (P == U);  
 if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *STM (User registers)* on page AppxA-4758.

## Assembler syntax

STM{<amode>}{<c>}{<q>} <Rn>, <registers>^

where:

<amode>	is one of:
DA	Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
ED	Empty Descending. For this instruction, a synonym for DA.
DB	Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
FD	Full Descending. For this instruction, a synonym for DB.
IA	Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
EA	Empty Ascending. For this instruction, a synonym for IA.
IB	Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
FA	Full Ascending. For this instruction, a synonym for IB.
<c>, <q>	See <a href="#">Standard assembler syntax fields on page F2-2415</a> .
<Rn>	The base register. This register can be the SP.
<registers>	Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be stored by the STM instruction. The registers are stored with the lowest-numbered register to the lowest memory address, through to the highest-numbered register to the highest memory address. See also <a href="#">Encoding of lists of general-purpose registers and the PC on page F2-2426</a> .

The pre-UAL syntax STM<c>{<amode>} is equivalent to STM{<amode>}<c>.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentModeIsHyp() then
        UNDEFINED;
    elsif CurrentModeIsUserOrSystem() then
        UNPREDICTABLE;
    else
        length = 4*BitCount(registers);
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address+4;
        for i = 0 to 14
            if registers<i> == '1' then // Store User mode register
                MemA[address,4] = Rmode[i, M32_User];
                address = address + 4;
            if registers<15> == '1' then
                MemA[address,4] = PCStoreValue();
  
```

### F7.4.18 STRBT, STRHT, and STRT

Even in Secure and Non-secure EL1 modes, stores to memory by these instructions are restricted in the same way as unprivileged stores to memory. The MemA\_unpriv[] and MemU\_unpriv[] pseudocode functions describe this restriction. For more information see [Alignment support on page E2-2341](#).

These instructions are UNPREDICTABLE in Hyp mode.

For descriptions of the instructions see:

- [STRBT on page F7-2890](#).
- [STRHT on page F7-2910](#).
- [STRT on page F7-2912](#).

### F7.4.19 SUBS PC, LR and related instructions (T32)

The SUBS PC, LR, #<const> instruction provides an exception return without the use of the stack. It subtracts the immediate constant from LR, branches to the resulting address, and also copies the SPSR to the CPSR.

———— **Note** —————

- The instruction SUBS PC, LR, #0 is equivalent to MOVS PC, LR and ERET.
- For an implementation that includes EL2, ERET is the preferred disassembly of the T1 encoding defined in this section. Therefore, a disassembler might report an ERET where the original assembler code used SUBS PC, LR, #0.

When executing in Hyp mode:

- The encoding for SUBS PC, LR, #0 is the encoding of the ERET instruction, see [ERET on page F7-3038](#).
- SUBS PC, LR, #<const> with a nonzero constant is UNDEFINED.

SUBS PC, LR, #<const> is CONSTRAINED UNPREDICTABLE in the cases described in [Restrictions on exception return instructions on page F7-3028](#).

**Encoding T1** ARMv6T2, ARMv7

SUBS<c> PC, LR, #<imm8> Outside or last in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	1	0	1	(1)	(1)	(1)	(0)	1	0	(0)	0	(1)	(1)	(1)	(1)	imm8							

```

if IsZero(imm8) then SEE ERET;
if CurrentInstrSet() == InstrSet_T32EE then UNPREDICTABLE;
if CurrentModeIsHyp() then UNDEFINED; // UNDEFINED in Hyp mode when not ERET
n = 14; imm32 = ZeroExtend(imm8, 32);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
    
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [SUBS PC, LR and related instructions \(T32\) on page AppxA-4758](#).

## Assembler syntax

SUBS{<c>}{<q>} PC, LR, #<const>

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2415.

<const> The immediate constant, in the range 0-255.

In the T32 instruction set, MOV{<c>}{<q>} PC, LR is a pseudo-instruction for SUBS{<c>}{<q>} PC, LR, #0.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if (CurrentModeIsUserOrSystem() || CurrentInstrSet() == InstrSet_T32EE) then
        UNPREDICTABLE;
    else
        operand2 = imm32;
        (result, -) = AddWithCarry(R[n], NOT(operand2), '1');
        CPSRWriteByInstr(SPSR[], '1111', TRUE);
        if CPSR.M == M32_Hyp && CPSR.J == '1' && CPSR.T == '1' then
            UNPREDICTABLE;
        else
            BranchWritePC(result);
```

## F7.4.20 SUBS PC, LR and related instructions (A32)

The SUBS PC, LR, #<const> instruction provides an exception return without the use of the stack. It subtracts the immediate constant from LR, branches to the resulting address, and also copies the SPSR to the CPSR. The A32 instruction set contains similar instructions based on other data-processing operations, or with a wider range of operands, or both. ARM deprecates using these other instructions, except for MOVS PC, LR.

All of these instructions are:

- UNDEFINED in Hyp mode.
- CONSTRAINED UNPREDICTABLE in the cases described in [Restrictions on exception return instructions on page F7-3028](#).

### Encoding A1 ARMv4\*, ARMv5T\*, ARMv6\*, ARMv7

            when '1111' result = NOT(operand2); // MVN

AArch32.ExceptionReturn(result, SPSR[]);

```

## F7.4.21 VMRS

Move to general-purpose register from Advanced SIMD and floating-point System register moves the value of an extension system register to a general-purpose register. When the specified floating-point System register is the **FPSCR**, a form of the instruction transfers the **FPSCR**.{N, Z, C, V} condition flags to the **APSR**.{N, Z, C, V} condition flags.

Depending on settings in the **CPACR**, **NSACR**, **HCPTR**, and **FPEXC** registers, and the security state and mode in which the instruction is executed, an attempt to execute a VMRS instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of general controls of CP10 and CP11 functionality on page G1-3496](#) and [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarize these controls.

When these settings permit the execution of floating-point and Advanced SIMD instructions, if the specified floating-point System register is not the **FPSCR**, the instruction is UNDEFINED if executed in User mode.

In an implementation that includes EL2, when **HCR.TID0** is set to 1, any VMRS access to **FPSID**, from a Non-secure EL1 mode, that would be permitted if **HCR.TID0** was set to 0, generates a Hyp Trap exception. For more information, see [ID group 0, Primary device identification registers on page G1-3507](#).

———— **Note** —————

- [VMRS on page F8-3232](#) describes the valid application level uses of the VMRS instruction
- For simplicity, the VMRS pseudocode does not show the possible trap to Hyp mode.

### Encoding T1/A1 VFPv2, VFPv3, VFPv4, Advanced SIMD

VMRS<c> <Rt>, <spec\_reg>

cond				1	1	1	0	1	1	1	1	reg				Rt	1	0	1	0	(0)	(0)	(0)	1	(0)	(0)	(0)	(0)			

```
t = UInt(Rt);
if t == 15 && reg != '0001' then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VMRS on page AppxA-4759](#).

## Assembler syntax

VMRS{<c>}{<q>} <Rt>, <spec\_reg>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rt> The destination general-purpose register. This register can be R0-R14.

If <spec\_reg> is FPSCR, it is also permitted to be APSR\_nzcv, encoded as Rt = '1111'. This instruction transfers the [FPSCR](#).{N, Z, C, V} condition flags to the [APSR](#).{N, Z, C, V} condition flags.

<spec\_reg> Is one of:

FPSID reg = '0000'.

FPSCR reg = '0001'.

MVFR1 reg = '0110'.

MVFR0 reg = '0111'.

FPEXC reg = '1000'.

If the Common VFP subarchitecture is implemented, see [Floating-point exception traps, serialization, and floating-point exception barriers on page G1-3501](#) for additional values of <spec\_reg>.

The pre-UAL instruction FMSTAT is equivalent to VMRS APSR\_nzcv, FPSCR.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if reg == '0001' then // FPSCR
        CheckVFPEEnabled(TRUE); SerializeVFP(); VFPEXCBarrier();
        if t == 15 then
            APSR.N = FPSR.N; APSR.Z = FPSR.Z; APSR.C = FPSR.C; APSR.V = FPSR.V;
        else
            R[t] = FPSCR;
    else // Non-FPSCR registers are accessible only at PL1 or above and not affected by FPEXC.EN
        CheckVFPEEnabled(FALSE);
        if !CurrentModeIsNotUser() then
            UNDEFINED;
        else
            case reg of
                when '0000' SerializeVFP(); R[t] = FPSID;
                // Pseudocode does not consider possible trap of Non-secure FPSID access to Hyp mode
                // '0001' already handled
                when '001x', '010x' UNPREDICTABLE;
                when '0110' SerializeVFP(); R[t] = MVFR1;
                when '0111' SerializeVFP(); R[t] = MVFR0;
                when '1000' SerializeVFP(); R[t] = FPEXC;
                otherwise SUBARCHITECTURE_DEFINED register access;
            end case
        end if
    end if
end if
  
```

## F7.4.22 VMSR

Move to Advanced SIMD and floating-point System register from general-purpose register moves the value of a general-purpose register to a floating-point System register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute a VMSR instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of general controls of CP10 and CP11 functionality on page G1-3496](#) and [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarize these controls.

When these settings permit the execution of floating-point and Advanced SIMD instructions, if the specified floating-point System register is not the [FPSCR](#), the instruction is UNDEFINED if executed in User mode.

———— **Note** —————

[VMSR on page F8-3234](#) describes the valid application level uses of the VMSR instruction.

```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VMSR on page AppxA-4759](#).

## Assembler syntax

VMSR{<c>}{<q>} <spec\_reg>, <Rt>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<spec\_reg> Is one of:

FPSID reg = '0000'.

FPSCR reg = '0001'.

FPEXC reg = '1000'.

If the Common VFP subarchitecture is implemented, see [Floating-point exception traps, serialization, and floating-point exception barriers on page G1-3501](#) for additional values of <spec\_reg>.

<Rt> The general-purpose register to be transferred to <spec\_reg>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if reg == '0001' then // FPSCR
        CheckVFPEnabled(TRUE); SerializeVFP(); VFPExcBarrier();
        FPSCR = R[t];
    else // Non-FPSCR registers are accessible only at PL1 or above and not affected by FPEXC.EN
        CheckVFPEnabled(FALSE);
        if !CurrentModeIsNotUser() then
            UNDEFINED;
        else
            case reg of
                // '001x', '01xx' dealt with in encoding-specific pseudocode
                // '0001' already dealt with above
                when '0000' SerializeVFP(); // FPSID is read-only
                when '1000' SerializeVFP(); FPEXC = R[t];
                otherwise SUBARCHITECTURE_DEFINED "register access";
```

# Chapter F8

## T32 and A32 Advanced SIMD and floating-point Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- [Alphabetical list of floating-point and Advanced SIMD instructions on page F8-3076.](#)

———— **Note** —————

Before ARMv8, the Advanced SIMD and floating-point instructions were added to the T32 and A32 instruction sets by the Advanced SIMD Extension and the Floating-point Extension, previously called VFP Extension. Instruction descriptions indicate the first version of the Floating-point extension (VFPv8) or Advanced SIMD Extension that included the instruction.

—————

## F8.1 Alphabetical list of floating-point and Advanced SIMD instructions

This section lists every floating-point and Advanced SIMD instruction in the T32 and A32 instruction sets. For details of the format used see [Format of instruction descriptions on page F2-2410](#).

This section is formatted so that a full description of an instruction uses either a single page or two facing pages.

### F8.1.1 AESD

AES single round decryption.

#### Encoding T1 ARMv8 Advanced SIMD

AESD.8 <Qd>, <Qm>

```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

### Assembler syntax

AESMC.8 <Qd>, <Qm>

where:

<Qd>, <Qm> The destination vector and the operand vector, for a quadword operation.

### Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    op1 = Q[d>>1]; op2 = Q[m>>1];
    Q[d>>1] = AESSubBytes(AESShiftRows(op1 EOR op2));
    
```

## F8.1.5 F\*, former floating-point instruction mnemonics

Before the introduction of UAL, the floating-point instructions had mnemonics starting with F. In UAL, most of these mnemonics are renamed to start with V. However, as this section describes, UAL does not define new mnemonics for the FLDMX and FSTMX instructions.

### FLDMX, FSTMX

Encodings T1/A1 of the VLDM, VPOP, VPUSH, and VSTM instructions contain an imm8 field that is set to twice the number of doubleword registers to be transferred. ARM deprecates use of these encodings with an odd value in imm8, and there is no UAL syntax for them.

The pre-UAL mnemonics FLDMX and FSTMX result in the same instructions as FLDMD (VLDM.64 or VPOP.64) and FSTMD (VSTM.64 or VPUSH.64) respectively, except that imm8 is equal to twice the number of doubleword registers plus one:

- From ARMv6, ARM deprecates use of FLDMX and FSTMX, except for disassembly purposes, and for reassembly of disassembled code.
- If an FLDMX or FSTMX instruction accesses any register in the range D16-D32, the instruction is UNPREDICTABLE.

## F8.1.6 SHA1C

SHA1 hash update (choose).

### Encoding T1 ARMv8 Advanced SIMD

SHA1C.32 <Qd>, <Qn>, <Qm>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

    Q[d>>1] = result;
```

## F8.1.16 VABA, VABAL

Vector Absolute Difference and Accumulate {Long} subtracts the elements of one vector from the corresponding elements of another vector, and accumulates the absolute values of the results into the elements of the destination vector.

Operand and result elements are either all integers of the same length, or optionally the results can be double the length of the operands.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a VFP instruction, see [Conditional execution on page F2-2416](#).

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[n+r],e,esize]; op2 = Elem[D[m+r],e,esize];
            Elem[D[d+r],e,esize] = FPAbs(FPSub(op1,op2,StandardFPCRValue()));
```

## F8.1.19 VABS

Vector Absolute takes the absolute value of each element in a vector, and places the results in a second vector. The floating-point version only clears the sign bit.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of general controls of CP10 and CP11 functionality on page G1-3496](#) and [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a VFP instruction, see [Conditional execution on page F2-2416](#).

            S[d] = FPAbs(S[m]);
  
```

## F8.1.20 VACGE, VACGT, VACLE, VACL

VACGE (Vector Absolute Compare Greater Than or Equal) and VACGT (Vector Absolute Compare Greater Than) take the absolute value of each element in a vector, and compare it with the absolute value of the corresponding element of a second vector. If the condition is true, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

VACLE (Vector Absolute Compare Less Than or Equal) is a pseudo-instruction, equivalent to a VACGE instruction with the operands reversed. Disassembly produces the VACGE instruction.

VACL (Vector Absolute Compare Less Than) is a pseudo-instruction, equivalent to a VACGT instruction with the operands reversed. Disassembly produces the VACGT instruction.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements must be 32-bit floating-point numbers.

The result vector elements are 32-bit fields.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

[Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a VFP instruction, see [Conditional execution on page F2-2416](#).

```

### F8.1.23 VADDHN

Vector Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are truncated. (For rounded results, see [VRADDHN](#) on page F8-3300).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] + Elem[Qin[m>>1],e,2*esize];
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

## F8.1.24 VADDL, VADDW

VADDL (Vector Add Long) adds corresponding elements in two doubleword vectors, and places the results in a quadword vector. Before adding, it sign-extends or zero-extends the elements of both operands.

VADDW (Vector Add Wide) adds corresponding elements in one quadword and one doubleword vector, and places the results in a quadword vector. Before adding, it sign-extends or zero-extends the elements of the doubleword operand.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VADDL or VADDW instruction must be unconditional. ARM strongly recommends that a T32 VADDL or VADDW instruction is unconditional, see [Conditional execution on page F2-2416](#).
- <dt> The data type for the elements of the second operand vector. It must be one of:
  - S8 Encoded as size = 0b00, U = 0.
  - S16 Encoded as size = 0b01, U = 0.
  - S32 Encoded as size = 0b10, U = 0.
  - U8 Encoded as size = 0b00, U = 1.
  - U16 Encoded as size = 0b01, U = 1.
  - U32 Encoded as size = 0b10, U = 1.
- <Qd> The destination register. If this register is omitted in a VADDW instruction, it is the same register as <Qn>.
- <Qn>, <Dm> The first and second operand registers for a VADDW instruction.
- <Dn>, <Dm> The first and second operand registers for a VADDL instruction.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        if is_vaddw then
            op1 = Int(Elem[Qin[n>>1],e,2*esize], unsigned);
        else
            op1 = Int(Elem[Din[n],e,esize], unsigned);
        result = op1 + Int(Elem[Din[m],e,esize], unsigned);
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
  
```

### F8.1.25 VAND (immediate)

This is a pseudo-instruction, equivalent to a VBIC (immediate) instruction with the immediate value bitwise inverted. For details see [VBIC \(immediate\)](#) on page F8-3112.

### F8.1.26 VAND (register)

This instruction performs a bitwise AND operation between two registers, and places the result in the destination register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality](#) on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution](#) on page F2-2416.

VAND{<C>}{<q>}{.<dt>} {<Dd>}, <Dn>, <Dm> Encoded as Q = 0

where:

<C>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VAND instruction must be unconditional. ARM strongly recommends that a T32 VAND instruction is unconditional, see [Conditional execution on page F2-2416](#).

<dt> An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd>, <Qn>, <Qm> The destination vector and the operand vectors, for a quadword operation.

<Dd>, <Dn>, <Dm> The destination vector and the operand vectors, for a doubleword operation.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] AND D[m+r];
```

### F8.1.27 VBIC (immediate)

Vector Bitwise Bit Clear (immediate) performs a bitwise AND between a register value and the complement of an immediate value, and returns the result into the destination vector. For the range of constants available, see *One register and a modified immediate value* on page F5-2508.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page F2-2416.

#### Encoding T1/A1 Advanced SIMDv1

VBIC<c>.<dt> <Qd>, #<imm>

VBIC<c>.<dt> <Dd>, #<imm>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1	1	1	1	0	0	1	i	1	D	0	0	0	imm3		Vd		cmode	0	Q	1	1		imm4								

```

if cmode<0> == '0' || cmode<3:2> == '11' then SEE "Related encodings";
if Q == '1' && Vd<0> == '1' then UNDEFINED;
imm64 = AdvSIMDEExpandImm('1', cmode, i:imm3:imm4);
d = UInt(D:Vd); regs = if Q == '0' then 1 else 2;
    
```

**Related encodings** See *One register and a modified immediate value* on page F5-2508.

## Assembler syntax

VBIC{<c>}{<q>}.<dt> {<Qd>}, <Qd>, #<imm> Encoded as Q = 1  
VBIC{<c>}{<q>}.<dt> {<Dd>}, <Dd>, #<imm> Encoded as Q = 0

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VBIC instruction must be unconditional. ARM strongly recommends that a T32 VBIC instruction is unconditional, see [Conditional execution on page F2-2416](#).

<dt> The data type used for <imm>. It can be either I16 or I32. I8, I64, and F32 are also permitted, but the resulting syntax is a pseudo-instruction.

<Qd> The destination vector for a quadword operation.

<Dd> The destination vector for a doubleword operation.

<imm> A constant of the type specified by <dt>. This constant is replicated enough times to fill the destination register. For example, VBIC.I32 D0, #10 ANDs the complement of 0x0000000A0000000A with D0, and puts the result into D0.

For details of the range of constants available and the encoding of <dt> and <imm>, see [One register and a modified immediate value on page F5-2508](#).

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[d+r] AND NOT(imm64);
```

## Pseudo-instructions

VAND can be used with a range of constants that are the bitwise inverse of the available constants for VBIC. This is assembled as the equivalent VBIC instruction. Disassembly produces the VBIC form.

[One register and a modified immediate value on page F5-2508](#) describes pseudo-instructions with a combination of <dt> and <imm> that is not supported by hardware, but that generates the same destination register value as a different combination that is supported by hardware.

## F8.1.28 VBIC (register)

Vector Bitwise Bit Clear (register) performs a bitwise AND between a register value and the complement of a register value, and places the result in the destination register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

    for r = 0 to regs-1
        D[d+r] = D[n+r] AND NOT(D[m+r]);
```

## F8.1.29 VBIF, VBIT, VBSL

VBIF (Vector Bitwise Insert if False), VBIT (Vector Bitwise Insert if True), and VBSL (Vector Bitwise Select) perform bitwise selection under the control of a mask, and place the results in the destination register. The registers can be either quadword or doubleword, and must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

```

### F8.1.30 VCEQ (register)

VCEQ (Vector Compare Equal) takes each element in a vector, and compares it with the corresponding element of a second vector. If they are equal, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

[Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

```

### F8.1.33 VCGE (immediate #0)

VCGE #0 (Vector Compare Greater Than or Equal to Zero) take each element in a vector, and compares it with zero. If it is greater than or equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

```

## F8.1.42 VCMP, VCMPE

This instruction compares two floating-point registers, or one floating-point register and zero. It writes the result to the **FPSCR** flags. These are normally transferred to the A32 flags by a subsequent **VMRS** instruction.

It can optionally raise an Invalid Operation exception if either operand is any type of NaN. It always raises an Invalid Operation exception if either operand is a signaling NaN.

Depending on settings in the **CPACR**, **NSACR**, and **HCPTR** registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of general controls of CP10 and CP11 functionality on page G1-3496](#) summarizes these controls.

VCMP{E}{<C>}{<Q>}.F32 <Sd>, #0.0	Encoding T2/A2, encoded as sz = 0

where:

E If present, any NaN operand causes an Invalid Operation exception. Encoded as E = 1.  
 Otherwise, only a signaling NaN causes the exception. Encoded as E = 0.

<C>, <Q> See [Standard assembler syntax fields on page F2-2415](#).

<Dd>, <Dm> The operand vectors, for a doubleword operation.

<Sd>, <Sm> The operand vectors, for a singleword operation.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    if dp_operation then
        bits(64) op64 = if with_zero then FPZero('0') else D[m];
        FPSCR.<N,Z,C,V> = FPCompare(D[d], op64, quiet_nan_exc, FPSCR);
    else
        bits(32) op32 = if with_zero then FPZero('0') else S[m];
        FPSCR.<N,Z,C,V> = FPCompare(S[d], op32, quiet_nan_exc, FPSCR);
  
```

## NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or *unordered*. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This results in the **FPSCR** flags being set as N=0, Z=0, C=1 and V=1.

VCMP<sub>E</sub> raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

### F8.1.43 VCNT

This instruction counts the number of bits that are one in each element in a vector, and places the results in a second vector.

The operand vector elements must be 8-bit fields.

The result vector elements are 8-bit integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

```

## F8.1.45 VCVT, VCVTR (between floating-point and integer, floating-point)

These instructions convert a value in a register from floating-point to a 32-bit integer, or from a 32-bit integer to floating-point, and place the result in a second register.

The floating-point to integer operation normally uses the Round towards Zero rounding mode, but can optionally use the rounding mode specified by the **FPSCR**. The integer to floating-point operation uses the rounding mode specified by the **FPSCR**.

*VCVT (between floating-point and fixed-point, floating-point)* on page F8-3148 describes conversions between floating-point and 16-bit integers.

Depending on settings in the **CPACR**, **NSACR**, and **HCPTR**, and **FPEXC** registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3496 summarizes these controls.

```

## F8.1.47 VCVT (between floating-point and fixed-point, floating-point)

This instruction converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point. Software can specify the fixed-point value as either signed or unsigned.

The floating-point value can be single-precision or double-precision.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality on page G1-3496* summarizes these controls.

        else
            S[d] = FixedToFP(S[d]<size-1:0>, frac_bits, unsigned, FPSCR, FPRounding_TIEEVEN);
  
```

## F8.1.48 VCVT (between double-precision and single-precision)

This instruction does one of the following:

- Converts the value in a double-precision register to single-precision and writes the result to a single-precision register.
- Converts the value in a single-precision register to double-precision and writes the result to a double-precision register.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality on page G1-3496* summarizes these controls.

**Encoding T1/A1** VFPv2, VFPv3, VFPv4 (UNDEFINED in single-precision only variants)

```

## F8.1.49 VCVT (between half-precision and single-precision, Advanced SIMD)

This instruction converts each element in a vector from single-precision to half-precision floating-point or from half-precision to single-precision, and places the results in a second vector.

The vector elements must be 32-bit floating-point numbers, or 16-bit floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

**Encoding T1/A1** Advanced SIMDv1 with Half-precision Extension (UNDEFINED in integer-only variant)

### Assembler syntax

VCVT{<c>}{<q>}.F32.F16 <Qd>, <Dm>

Encoded as op = 1

VCVT{<c>}{<q>}.F16.F32 <Dd>, <Qm>

Encoded as op = 0

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VCVT instruction must be unconditional. ARM strongly recommends that a T32 VCVT instruction is unconditional, see [Conditional execution on page F2-2416](#).

<Qd>, <Dm> The destination vector and the operand vector for a half-precision to single-precision operation.

<Dd>, <Qm> The destination vector and the operand vectors for a single-precision to half-precision operation.

### Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        if half_to_single then
            Elem[Q[d>>1],e,32] = FPConvert(Elem[Din[m],e,16], StandardFPSCRValue());
        else
            Elem[D[d],e,16] = FPConvert(Elem[Qin[m>>1],e,32], StandardFPSCRValue());
    
```

### F8.1.50 VCVTA, VCVTN, VCVTP, VCVTM (between floating-point and integer, Advanced SIMD)

These instructions convert each element in a vector from floating-point to integer and places the results in a second vector.

The vector elements must be 32-bit floating-point numbers, or 32-bit integers. Signed and unsigned integers are distinct.

These instructions use the following rounding modes:

- VCVTA: Round to Nearest with Ties to Away.
- VCVTN: Round to Nearest with Ties to Even.
- VCVTP: Round toward +Infinity.
- VCVTM: Round toward -Infinity.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality on page G1-3496* summarizes these controls.

```

## F8.1.54 VDUP (scalar)

Vector Duplicate duplicates a scalar into every element of the destination vector.

The scalar, and the destination vector elements, can be any one of 8-bit, 16-bit, or 32-bit fields. There is no distinction between data types.

For more information about scalars see [Advanced SIMD scalars on page F5-2498](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

VDUP{<c>}{<q>}.<size> <Dd>, <Dm[x]> Encoded as Q = 0

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VDUP instruction must be unconditional. ARM strongly recommends that a T32 VDUP instruction is unconditional, see [Conditional execution on page F2-2416](#).

<size> The data size. It must be one of:

8	Encoded as imm4<0> = '1'. imm4<3:1> encodes the index [x] of the scalar.
16	Encoded as imm4<1:0> = '10'. imm4<3:2> encodes the index [x] of the scalar.
32	Encoded as imm4<2:0> = '100'. imm4<3> encodes the index [x] of the scalar.

<Qd> The destination vector for a quadword operation.

<Dd> The destination vector for a doubleword operation.

<Dm[x]> The scalar. For details of how [x] is encoded, see the description of <size>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    scalar = Elem[D[m],index,esize];
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = scalar;
```

### F8.1.55 VDUP (general-purpose register)

This instruction duplicates an element from a general-purpose register into every element of the destination vector.

The destination vector elements can be 8-bit, 16-bit, or 32-bit fields. The source element is the least significant 8, 16, or 32 bits of the general-purpose register. There is no distinction between data types.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

[Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

VDUP{<c>}{<q>}.<size> <Qd>, <Rt> Encoded as Q = 1  
VDUP{<c>}{<q>}.<size> <Dd>, <Rt> Encoded as Q = 0

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). ARM strongly recommends that any VDUP instruction is unconditional, see [Conditional execution on page F2-2416](#).

<size> The data size for the elements of the destination vector. It must be one of:  
8 Encoded as [b, e] = 0b10.  
16 Encoded as [b, e] = 0b01.  
32 Encoded as [b, e] = 0b00.

<Qd> The destination vector for a quadword operation.

<Dd> The destination vector for a doubleword operation.

<Rt> The ARM source register.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    scalar = R[t]<size-1:0>;
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = scalar;
```

## F8.1.56 VEOR

Vector Bitwise Exclusive OR performs a bitwise Exclusive OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

### Encoding T1/A1 Advanced SIMDv1

 d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;

## Assembler syntax

VEOR{<c>}{<q>}{.<dt>} {<Qd>}, <Qn>, <Qm> Encoded as Q = 1  
VEOR{<c>}{<q>}{.<dt>} {<Dd>}, <Dn>, <Dm> Encoded as Q = 0

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VEOE instruction must be unconditional. ARM strongly recommends that a T32 VEOE instruction is unconditional, see [Conditional execution on page F2-2416](#).

<dt> An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd>, <Qn>, <Qm> The destination vector and the operand vectors, for a quadword operation.

<Dd>, <Dn>, <Dm> The destination vector and the operand vectors, for a doubleword operation.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] EOR D[m+r];
```

### F8.1.57 VEXT

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector. See [Figure F8-1](#) for an example.

The elements of the vectors are treated as being 8-bit fields. There is no distinction between data types.

**Figure F8-1 VEXT doubleword operation for imm = 3**

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

[Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

#### Encoding T1/A1 Advanced SIMDv1

VEXT<c>.8 <Qd>, <Qn>, <Qm>, #<imm>

VEXT<c>.8 <Dd>, <Dn>, <Dm>, #<imm>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if Q == '0' && imm4<3> == '1' then UNDEFINED;
quadword_operation = (Q == '1'); position = 8 * UInt(imm4);
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
    
```

## Assembler syntax

VEXT{<c>}{<q>}.<size> {<Qd>}, <Qn>, <Qm>, #<imm> Encoded as Q = 1  
 VEXT{<c>}{<q>}.<size> {<Dd>}, <Dn>, <Dm>, #<imm> Encoded as Q = 0

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VEXT instruction must be unconditional. ARM strongly recommends that a T32 VEXT instruction is unconditional, see [Conditional execution on page F2-2416](#).

<size> Size of the operation. The value can be:

- 8, 16, or 32 for doubleword operations.
- 8, 16, 32, or 64 for quadword operations.

If the value is 16, 32, or 64, the syntax is a pseudo-instruction for a VEXT instruction specifying the equivalent number of bytes. The following examples show how an assembler treats values greater than 8:

VEXT.16 D0, D1, #x is treated as VEXT.8 D0, D1, #(x\*2).  
 VEXT.32 D0, D1, #x is treated as VEXT.8 D0, D1, #(x\*4).  
 VEXT.64 Q0, Q1, #x is treated as VEXT.8 Q0, Q1, #(x\*8).

<Qd>, <Qn>, <Qm> The destination vector and the operand vectors, for a quadword operation.

<Dd>, <Dn>, <Dm> The destination vector and the operand vectors, for a doubleword operation.

<imm> The location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0-7 for a doubleword operation or 0-15 for a quadword operation.

## Operation

```
if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  if quadword_operation then
    Q[d>1] = (Q[m>1]:Q[n>1])<position+127:position>;
  else
    D[d] = (D[m]:D[n])<position+63:position>;
```

## F8.1.58 VFMA, VFMS

Vector Fused Multiply Accumulate multiplies corresponding elements of two vectors, and accumulates the results into the elements of the destination vector. The instruction does not round the result of the multiply before the accumulation.

Vector Fused Multiply Subtract negates the elements of one vector and multiplies them with the corresponding elements of another vector, adds the products to the corresponding elements of the destination vector, and places the results in the destination vector. The instruction does not round the result of the multiply before the addition.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality on page G1-3496* and *Summary of access controls for Advanced SIMD functionality on page G1-3498* summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution on page F2-2416*.

```

## F8.1.60 VHADD, VHSUB

Vector Halving Add adds corresponding elements in two vectors of integers, shifts each result right one bit, and places the final results in the destination vector. The results of the halving operations are truncated (for rounded results see [VRHADD](#) on page F8-3308).

Vector Halving Subtract subtracts the elements of the second operand from the corresponding elements of the first operand, shifts each result right one bit, and places the final results in the destination vector. The results of the halving operations are truncated (there is no rounding version).

The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality](#) on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution](#) on page F2-2416.

```

## F8.1.61 VLD1 (multiple single elements)

This instruction loads elements from memory into one, two, three, or four registers, without de-interleaving. Every element of each register is loaded. For details of the addressing mode see [Advanced SIMD addressing mode on page F5-2517](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

### Encoding T1/A1 Advanced SIMDv1

- <list> The registers containing the structure. Encoded with D:Vd = <Dd>. It must be one of:  
 {<Dd[x]>, <Dd+1[x]>} Single-spaced registers, see [Table F8-2](#).  
 {<Dd[x]>, <Dd+2[x]>} Double-spaced registers, see [Table F8-2](#).  
 This is not available if <size> == 8.
- <Rn> Contains the base address for the access.
- <align> The alignment. It can be one of:  
 16 2-byte alignment, available only if <size> is 8.  
 32 4-byte alignment, available only if <size> is 16.  
 64 8-byte alignment, available only if <size> is 32.  
**omitted** Standard alignment, see [Unaligned data access on page E2-2341](#).  
 : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode on page F5-2517](#).
- ! If present, specifies writeback.
- <Rm> Contains an address offset applied after the access.

For more information about <Rn>, !, and <Rm> see [Advanced SIMD addressing mode on page F5-2517](#).

**Table F8-2 Encoding of index, alignment, and register spacing**

	<size> == 8	<size> == 16	<size> == 32
Index	index_align[3:1] = x	index_align[3:2] = x	index_align[3] = x
Single-spacing	-	index_align[1] = 0	index_align[2] = 0
Double-spacing	-	index_align[1] = 1	index_align[2] = 1
<align> omitted	index_align[0] = 0	index_align[0] = 0	index_align[1:0] = '00'
<align> == 16	index_align[0] = 1	-	-
<align> == 32	-	index_align[0] = 1	-
<align> == 64	-	-	index_align[1:0] = '01'

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled(); NullCheckIfThumbEE(n);
    address = R[n]; if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 2*ebytes);
    Elem[D[d], index] = MemU[address,ebytes];
    Elem[D[d2],index] = MemU[address+ebytes,ebytes];
    
```

### F8.1.66 VLD2 (single 2-element structure to all lanes)

This instruction loads one 2-element structure from memory into all lanes of two registers. For details of the addressing mode see [Advanced SIMD addressing mode on page F5-2517](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

<Rn>	Contains the base address for the access.
<align>	The alignment. It can be one of: 64            8-byte alignment, encoded as align = 0b01. 128          16-byte alignment, encoded as align = 0b10. 256          32-byte alignment, encoded as align = 0b11. <b>omitted</b> Standard alignment, see <a href="#">Unaligned data access on page E2-2341</a> . Encoded as align = 0b00. : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see <a href="#">Advanced SIMD addressing mode on page F5-2517</a> .
!	If present, specifies writeback.
<Rm>	Contains an address offset applied after the access.

For more information about <Rn>, !, and <Rm>, see [Advanced SIMD addressing mode on page F5-2517](#).

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled(); NullCheckIfThumbEE(n);
    address = R[n]; if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 32);
    for e = 0 to elements-1
        Elem[D[d], e] = MemU[address,ebytes];
        Elem[D[d2],e] = MemU[address+ebytes,ebytes];
        Elem[D[d3],e] = MemU[address+2*ebytes,ebytes];
        Elem[D[d4],e] = MemU[address+3*ebytes,ebytes];
        address = address + 4*ebytes;
    
```

## F8.1.71 VLD4 (single 4-element structure to one lane)

This instruction loads one 4-element structure from memory into corresponding elements of four registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode see [Advanced SIMD addressing mode on page F5-2517](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = TRUE; add = (U == '1'); wback = (W == '1'); d = UInt(Vd:D); n = UInt(Rn);
imm32 = ZeroExtend(imm8:'00', 32); regs = UInt(imm8);
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
    
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLDM on page AppxA-4748](#).

**Related encodings** See [64-bit transfers between general-purpose and extension registers on page F5-2519](#).

**FLDMX** Encoding T1/A1 behaves as described by the pseudocode if imm8 is odd. However, there is no UAL syntax for such encodings and ARM deprecates their use. For more information, see [FLDMX, FSTMX on page F8-3080](#).

## Assembler syntax

VLDM{<mode>}{<c>}{<q>}{.<size>} <Rn>{!}, <list>

where:

<mode>	The addressing mode:
IA	Increment After. The consecutive addresses start at the address specified in <Rn>. This is the default and can be omitted. Encoded as P = 0, U = 1.
DB	Decrement Before. The consecutive addresses end just before the address specified in <Rn>. Encoded as P = 1, U = 0.
<c>, <q>	See <i>Standard assembler syntax fields</i> on page F2-2415.
<size>	An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers in <list>.
<Rn>	The base register. The SP can be used. In the A32 instruction set, if ! is not specified the PC can be used.
!	Causes the instruction to write a modified value back to <Rn>. This is required if <mode> == DB, and is optional if <mode> == IA. Encoded as W = 1. If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.
<list>	The extension registers to be loaded, as a list of consecutively numbered doubleword (encoding T1/A1) or singleword (encoding T2/A2) registers, separated by commas and surrounded by brackets. It is encoded in the instruction by setting D and Vd to specify the first register in the list, and imm8 to twice the number of registers in the list (encoding T1/A1) or the number of registers in the list (encoding T2/A2). <list> must contain at least one register. If it contains doubleword registers it must not contain more than 16 registers.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE); NullCheckIfThumbEE(n);
    address = if add then R[n] else R[n]-imm32;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            S[d+r] = MemA[address,4]; address = address+4;
        else
            word1 = MemA[address,4]; word2 = MemA[address+4,4]; address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian() then word1:word2 else word2:word1;
  
```

## F8.1.74 VLDR

This instruction loads a single extension register from memory, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality on page G1-3496* and *Summary of access controls for Advanced SIMD functionality on page G1-3498* summarize these controls.

## Assembler syntax

VLDR{<c>}{<q>}{.64} <Dd>, [<Rn> {, #+/-<imm>}]	Encoding T1/A1, immediate form
VLDR{<c>}{<q>}{.64} <Dd>, <label>	Encoding T1/A1, normal literal form
VLDR{<c>}{<q>}{.64} <Dd>, [PC, #+/-<imm>]	Encoding T1/A1, alternative literal form
VLDR{<c>}{<q>}{.32} <Sd>, [<Rn> {, #+/-<imm>}]	Encoding T2/A2, immediate form
VLDR{<c>}{<q>}{.32} <Sd>, <label>	Encoding T2/A2, normal literal form
VLDR{<c>}{<q>}{.32} <Sd>, [PC, #+/-<imm>]	Encoding T2/A2, alternative literal form

where:

<c>, <q>	See <a href="#">Standard assembler syntax fields on page F2-2415</a> .
.32, .64	Optional data size specifiers.
<Dd>	The destination register for a doubleword load.
<Sd>	The destination register for a singleword load.
<Rn>	The base register. The SP can be used.
+/-	Is + or omitted if the immediate offset is to be added to the base register value (add == TRUE), or – if it is to be subtracted (add == FALSE). #0 and #-0 generate different instructions.
<imm>	The immediate offset used for forming the address. For the immediate forms of the syntax, <imm> can be omitted, in which case the #0 form of the instruction is assembled. Permitted values are multiples of 4 in the range 0 to 1020.
<label>	The label of the literal data item to be loaded. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values are multiples of 4 in the range -1020 to 1020.  If the offset is zero or positive, imm32 is equal to the offset and add == TRUE. If the offset is negative, imm32 is equal to minus the offset and add == FALSE.

For the literal forms of the instruction, the base register is encoded as 0b1111 to indicate that the PC is the base register.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2380](#).

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE); NullCheckIfThumbEE(n);

        D[d] = if BigEndian() then word1:word2 else word2:word1;
  
```

## F8.1.75 VMAX, VMIN (integer)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

[Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

            else
                Elem[D[d+r],e,esize] = FPMin(op1, op2, StandardFPSCRValue());
  
```

## Floating-point maximum and minimum

- $\max(+0.0, -0.0) = +0.0$
- $\min(+0.0, -0.0) = -0.0$
- If any input is a NaN, the corresponding result element is the default NaN.

## F8.1.77 VMAXNM, VMINNM

These instructions determine the floating-point maximum number and floating point minimum number accordingly.

They handle NaNs in consistence with the IEEE754-2008 specification. They return the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to VFP VMAX and VMIN.

These instructions are not conditional.

```

## F8.1.79 VMLA, VMLS (floating-point)

Vector Multiply Accumulate multiplies corresponding elements in two vectors, and accumulates the results into the elements of the destination vector.

Vector Multiply Subtract multiplies corresponding elements in two vectors, subtracts the products from corresponding elements of the destination vector, and places the results in the destination vector.

### ———— Note —————

ARM recommends that software does not use the VMLS instruction in the *Round towards Plus Infinity* and *Round towards Minus Infinity* rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality on page G1-3496* and *Summary of access controls for Advanced SIMD functionality on page G1-3498* summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution on page F2-2416*.

```

## F8.1.80 VMLA, VMLAL, VMLS, VMLSL (by scalar)

Vector Multiply Accumulate and Vector Multiply Subtract multiply elements of a vector by a scalar, and either add the products to, or subtract them from, corresponding elements of the destination vector. Vector Multiply Accumulate Long and Vector Multiply Subtract Long do the same thing, but with destination vector elements that are twice as long as the elements that are multiplied.

For more information about scalars see [Advanced SIMD scalars on page F5-2498](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

S16 Encoded as U = 0, opc1<1> = 0, opc2<0> = 1. [x] is encoded in opc1<0>, opc2<1>.

U8 Encoded as U = 1, opc1<1> = 1. [x] is encoded in opc1<0>, opc2.

U16 Encoded as U = 1, opc1<1> = 0, opc2<0> = 1. [x] is encoded in opc1<0>, opc2<1>.

32 Encoded as U = 0, opc1<1> = 0, opc2 = 0b00. [x] is encoded in opc1<0>.

**omitted** Equivalent to 32.

<Dn[x]> The scalar. For details of how [x] is encoded see the description of <dt>.

<Rt> The destination general-purpose register.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDorVFPEEnabled(TRUE, advsimd);
    if unsigned then
        R[t] = ZeroExtend(Elem[D[n],index,esize], 32);
    else
        R[t] = SignExtend(Elem[D[n],index,esize], 32);
```

### F8.1.85 VMOV (between general-purpose register and single-precision register)

This instruction transfers the contents of a single-precision Floating-point register to a general-purpose register, or the contents of a general-purpose register to a single-precision Floating-point register.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of general controls of CP10 and CP11 functionality on page G1-3496](#) summarizes these controls.

#### Encoding T1/A1 VFPv2, VFPv3, VFPv4

    EncodingSpecificOperations(); CheckVFPEEnabled(TRUE);
    if to_arm_register then
        R[t] = S[n];
    else
        S[n] = R[t];
```

### F8.1.86 VMOV (between two general-purpose registers and two single-precision registers)

This instruction transfers the contents of two consecutively numbered single-precision Floating-point registers to two general-purpose registers, or the contents of two general-purpose registers to a pair of single-precision floating-point registers. The general-purpose registers do not have to be contiguous.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality on page G1-3496* summarizes these controls.

    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    if to_arm_registers then
        R[t] = D[m]<31:0>;
        R[t2] = D[m]<63:32>;
    else
        D[m]<31:0> = R[t];
        D[m]<63:32> = R[t2];
```

## F8.1.88 VMOVL

Vector Move Long takes each element in a doubleword vector, sign or zero-extends them to twice their original length, and places the results in a quadword vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

### Encoding T1/A1 Advanced SIMDv1

## Assembler syntax

`VMOVL{<c>}{<q>}.dt <Qd>, <Dm>`

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VMOVL instruction must be unconditional. ARM strongly recommends that a T32 VMOVL instruction is unconditional, see [Conditional execution on page F2-2416](#).

<dt> The data type for the elements of the operand. It must be one of:

S8	Encoded as U = 0, imm3 = 0b001.
S16	Encoded as U = 0, imm3 = 0b010.
S32	Encoded as U = 0, imm3 = 0b100.
U8	Encoded as U = 1, imm3 = 0b001.
U16	Encoded as U = 1, imm3 = 0b010.
U32	Encoded as U = 1, imm3 = 0b100.

<Qd>, <Dm> The destination vector and the operand vector.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Int(Elem[Din[m],e,esize], unsigned);
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
```

## F8.1.89 VMOVN

Vector Move and Narrow copies the least significant half of each element of a quadword vector into the corresponding elements of a doubleword vector.

The operand vector elements can be any one of 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

t = UInt(Rt);  
 // ARMv8-A removes UNPREDICTABLE for R13

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

VMRS{<c>}{<q>} <Rt>, FPSCR

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2415.

<Rt> The destination general-purpose register. This register can be R0-R14 or APSR\_nzcv. APSR\_nzcv is encoded as Rt = 0b1111, and the instruction transfers the FPSCR.{N, Z, C, V} condition flags to the APSR.{N, Z, C, V} condition flags.

The pre-UAL instruction FMSTAT is equivalent to VMRS APSR\_nzcv, FPSCR.

## Operation

```
if ConditionPassed() then
  EncodingSpecificOperations(); CheckVFPEEnabled(TRUE);
  SerializeVFP(); VFPExcBarrier();
  if t != 15 then
    R[t] = FPSCR;
  else
    APSR.N = FPSR.N;
    APSR.Z = FPSR.Z;
    APSR.C = FPSR.C;
    APSR.V = FPSR.V;
```

## F8.1.91 VMSR

Move to Advanced SIMD and floating-point System register from general-purpose register moves the value of a general-purpose register to the **FPSCR**.

For details of system level use of this instruction, see [VMSR on page F7-3072](#).

Depending on settings in the **CPACR**, **NSACR**, and **HCPTR**, and **FPEXC** registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of general controls of CP10 and CP11 functionality on page G1-3496](#) and [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarize these controls.

### Encoding T1/A1 VFPv2, VFPv3, VFPv4, Advanced SIMDv1

```
t = UInt(Rt);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

VMSR{<c>}{<q>} FPSCR, <Rt>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#).

<Rt> The general-purpose register to be transferred to the FPSCR.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEEnabled(TRUE);
    SerializeVFP(); VFPExcBarrier();
    FPSCR = R[t];
```

## F8.1.92 VMUL, VMULL (integer and polynomial)

Vector Multiply multiplies corresponding elements in two vectors. Vector Multiply Long does the same thing, but with destination vector elements that are twice as long as the elements that are multiplied.

For information about multiplying polynomials see [Polynomial arithmetic over {0, 1}](#) on page A1-45.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

U Encoded as op = 0 in both encodings, with U = 1 in encoding T2/A2. I Encoding T1/A1 only, encoded as op = 0. P Encoded as op = 1 in both encodings, with U = 0 in encoding T2/A2. When <type> is P, <size> must be 8 or 64
<size>	The data size for the elements of the operands. For integer types, it must be one of: 8 Encoded as size = 0b00. 16 Encoded as size = 0b01. 32 Encoded as size = 0b10. For polynomial types, it must be one of: 8 Encoded as size = 0b00. 32 Encoded as size = 0b10.
<Qd>, <Qn>, <Qm>	The destination vector and the operand vectors, for a quadword operation.
<Dd>, <Dn>, <Dm>	The destination vector and the operand vectors, for a doubleword operation.
<Qd>, <Dn>, <Dm>	The destination vector and the operand vectors, for a long operation.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize]; op1val = Int(op1, unsigned);
            op2 = Elem[Din[m+r],e,esize]; op2val = Int(op2, unsigned);
            if polynomial then
                product = PolynomialMult(op1,op2);
            else
                product = (op1val*op2val)<2*esize-1:0>;
            if long_destination then
                Elem[Q[d>>1],e,2*esize] = product;
            else
                Elem[D[d+r],e,esize] = product<esize-1:0>;
  
```

### F8.1.93 VMUL (floating-point)

Vector Multiply multiplies corresponding elements in two vectors, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality on page G1-3496 and Summary of access controls for Advanced SIMD functionality on page G1-3498* summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution on page F2-2416*.

```

## F8.1.94 VMUL, VMULL (by scalar)

Vector Multiply multiplies each element in a vector by a scalar, and places the results in a second vector. Vector Multiply Long does the same thing, but with destination vector elements that are twice as long as the elements that are multiplied.

For more information about scalars see [Advanced SIMD scalars on page F5-2498](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

```

## F8.1.95 VMVN (immediate)

Vector Bitwise NOT (immediate) places the bitwise inverse of an immediate integer constant into every element of the destination register. For the range of constants available, see [One register and a modified immediate value on page F5-2508](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

### Encoding T1/A1 Advanced SIMDv1

VMVN<c>.<dt> <Qd>, #<imm>

VMVN<c>.<dt> <Dd>, #<imm>

1	1	1	1	0	0	1	i	1	D	0	0	0	imm3			Vd		cmode		0	Q	1	1	imm4							

```

if (cmode<0> == '1' && cmode<3:2> != '11') || cmode<3:1> == '111' then SEE "Related encodings";
if Q == '1' && Vd<0> == '1' then UNDEFINED;
imm64 = AdvSIMDExpandImm('1', cmode, i:imm3:imm4);
d = UInt(D:Vd); regs = if Q == '0' then 1 else 2;
    
```

**Related encodings** See [One register and a modified immediate value on page F5-2508](#).

## Assembler syntax

VMVN{<c>}{<q>}.dt <Qd>, #<imm> Encoding T1/A1, encoded as Q = 1  
VMVN{<c>}{<q>}.dt <Dd>, #<imm> Encoding T1/A1, encoded as Q = 0

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VMVN instruction must be unconditional. ARM strongly recommends that a T32 VMVN instruction is unconditional, see [Conditional execution on page F2-2416](#).

<dt> The data type. It must be either I16 or I32.

<Qd> The destination register for a quadword operation.

<Dd> The destination register for a doubleword operation.

<imm> A constant of the specified type.

See [One register and a modified immediate value on page F5-2508](#) for the range of constants available, and the encoding of <dt> and <imm>.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = NOT(imm64);
```

## Pseudo-instructions

[One register and a modified immediate value on page F5-2508](#) describes pseudo-instructions with a combination of <dt> and <imm> that is not supported by hardware, but that generates the same destination register value as a different combination that is supported by hardware.

### F8.1.96 VMVN (register)

Vector Bitwise NOT (register) takes a value from a register, inverts the value of each bit, and places the result in the destination register. The registers can be either doubleword or quadword.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

            D[d] = FPNeg(D[m]);
        else
            S[d] = FPNeg(S[m]);
  
```

## F8.1.98 VNMLA, VNMLS, VNMUL

VNMLA multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the negation of the product, and writes the result back to the destination register.

VNMLS multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the product, and writes the result back to the destination register.

VNMUL multiplies together two floating-point register values, and writes the negation of the result to the destination register.

### ———— Note ————

ARM recommends that software does not use the VNMLA instruction in the *Round towards Plus Infinity* and *Round towards Minus Infinity* rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of general controls of CP10 and CP11 functionality on page G1-3496](#) summarizes these controls.

### F8.1.99 VORN (immediate)

VORN (immediate) is a pseudo-instruction, equivalent to a VORR (immediate) instruction with the immediate value bitwise inverted. For details see [VORR \(immediate\)](#) on page F8-3252.

### F8.1.100 VORN (register)

This instruction performs a bitwise OR NOT operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality](#) on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution](#) on page F2-2416.

VORN{<C>}{<q>}{.<dt>} {<Dd>}, <Dn>, <Dm> Encoded as Q = 0

where:

<C>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VORN instruction must be unconditional. ARM strongly recommends that a T32 VORN instruction is unconditional, see [Conditional execution on page F2-2416](#).

<dt> An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd>, <Qn>, <Qm> The destination vector and the operand vectors, for a quadword operation.

<Dd>, <Dn>, <Dm> The destination vector and the operand vectors, for a doubleword operation.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] OR NOT(D[m+r]);
```

### F8.1.101 VORR (immediate)

This instruction takes the contents of the destination vector, performs a bitwise OR with an immediate constant, and returns the result into the destination vector. For the range of constants available, see [One register and a modified immediate value on page F5-2508](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

#### Encoding T1/A1 Advanced SIMDv1

VORR<c>.<dt> <Qd>, #<imm>

VORR<c>.<dt> <Dd>, #<imm>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

if cmode<0> == '0' || cmode<3:2> == '11' then SEE VMOV (immediate);
if Q == '1' && Vd<0> == '1' then UNDEFINED;
imm64 = AdvSIMDExpandImm('0', cmode, i:imm3:imm4);
d = UInt(D:Vd); regs = if Q == '0' then 1 else 2;
    
```

## Assembler syntax

VORR{<c>}{<q>}.<dt> {<Qd>}, <Qd>, #<imm> Encoded as Q = 1  
VORR{<c>}{<q>}.<dt> {<Dd>}, <Dd>, #<imm> Encoded as Q = 0

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VORR instruction must be unconditional. ARM strongly recommends that a T32 VORR instruction is unconditional, see [Conditional execution on page F2-2416](#).

<dt> The data type used for <imm>. It can be either I16 or I32. I8, I64, and F32 are also permitted, but the resulting syntax is a pseudo-instruction.

<Qd> The destination vector for a quadword operation.

<Dd> The destination vector for a doubleword operation.

<imm> A constant of the type specified by <dt>. This constant is replicated enough times to fill the destination register. For example, VORR.I32 D0, #10 ORs 0x0000000A0000000A into D0.

For details of the range of constants available, and the encoding of <dt> and <imm>, see [One register and a modified immediate value on page F5-2508](#).

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[d+r] OR imm64;
```

## Pseudo-instructions

VORN can be used, with a range of constants that are the bitwise inverse of the available constants for VORR. This is assembled as the equivalent VORR instruction. Disassembly produces the VORR form.

[One register and a modified immediate value on page F5-2508](#) describes pseudo-instructions with a combination of <dt> and <imm> that is not supported by hardware, but that generates the same destination register value as a different combination that is supported by hardware.

### F8.1.102 VORR (register)

This instruction performs a bitwise OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

    for r = 0 to regs-1
        D[d+r] = D[n+r] OR D[m+r];
```

### F8.1.103 VPADAL

Vector Pairwise Add and Accumulate Long adds adjacent pairs of elements of a vector, and accumulates the results into the elements of the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

Figure F8-2 shows an example of the operation of VPADAL.

Figure F8-2 VPADAL doubleword operation for data type S16

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

            result = Int(op1, unsigned) + Int(op2, unsigned);
            Elem[D[d+r],e,2*esize] = Elem[D[d+r],e,2*esize] + result;
  
```

### F8.1.104 VPADD (integer)

Vector Pairwise Add (integer) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements must all be the same type, and can be 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

Figure F8-3 shows an example of the operation of VPADD.

Figure F8-3 VPADD operation for data type I16

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

        Elem[dest,e+h,esize] = Elem[D[m],2*e,esize] + Elem[D[m],2*e+1,esize];

    D[d] = dest;
  
```

### F8.1.105 VPADD (floating-point)

Vector Pairwise Add (floating-point) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements are 32-bit floating-point numbers.

Figure F8-3 on page F8-3258 shows an example of the operation of VPADD.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

## Assembler syntax

VPADD{<c>}{<q>}.F32 {<Dd>}, <Dn>, <Dm> Encoded as Q = 0, sz = 0

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VPADD instruction must be unconditional. ARM strongly recommends that a T32 VPADD instruction is unconditional, see [Conditional execution on page F2-2416](#).

<Dd>, <Dn>, <Dm> The destination vector, the first operand vector, and the second operand vector.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;

    for e = 0 to h-1
        Elem[dest,e,esize] = FPAdd(Elem[D[n],2*e,esize], Elem[D[n],2*e+1,esize], StandardFPSCRValue());
        Elem[dest,e+h,esize] = FPAdd(Elem[D[m],2*e,esize], Elem[D[m],2*e+1,esize], StandardFPSCRValue());

    D[d] = dest;
```

## F8.1.106 VPADDL

Vector Pairwise Add Long adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

Figure F8-4 shows an example of the operation of VPADDL.

Figure F8-4 VPADDL doubleword operation for data type S16

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

cond		1	1	0	0	1	D	1	1	1	1	0	1	Vd	1	0	1	1	imm8												

```
single_regs = FALSE; d = UInt(D:Vd); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FLDMX".
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if VFPSmallRegisterBank() && (d+regs) > 16 then UNPREDICTABLE;
```

### Encoding T2/A2 VFPv2, VFPv3, VFPv4

VPOP <list> <list> is consecutive 32-bit registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	0	0	1	D	1	1	1	1	0	1	Vd	1	0	1	0	imm8										

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		1	1	0	0	1	D	1	1	1	1	0	1	Vd	1	0	1	0	imm8												

```
single_regs = TRUE; d = UInt(Vd:D); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8);
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VPOP* on page AppxA-4748.

### FLDMX

Encoding T1/A1 behaves as described by the pseudocode if imm8 is odd. However, there is no UAL syntax for such encodings and ARM deprecates their use. For more information, see *FLDMX, FSTMX* on page F8-3080.

## Assembler syntax

VPOP{<c>}{<q>}{.<size>} <list>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <size> An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers in <list>.
- <list> The extension registers to be loaded, as a list of consecutively numbered doubleword (encoding T1/A1) or singleword (encoding T2/A2) registers, separated by commas and surrounded by brackets. It is encoded in the instruction by setting D and Vd to specify the first register in the list, and imm8 to twice the number of registers in the list (encoding T1/A1) or the number of registers in the list (encoding T2/A2). <list> must contain at least one register, and not more than sixteen.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE); NullCheckIfThumbEE(13);
    address = SP;
    SP = SP + imm32;
    if single_regs then
        for r = 0 to regs-1
            S[d+r] = MemA[address,4]; address = address+4;
    else
        for r = 0 to regs-1
            word1 = MemA[address,4]; word2 = MemA[address+4,4]; address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian() then word1:word2 else word2:word1;
```

## F8.1.110 VPUSH

Vector Push stores multiple consecutive extension registers to the stack.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality on page G1-3496* and *Summary of access controls for Advanced SIMD functionality on page G1-3498* summarize these controls.

### Encoding T1/A1 VFPv2, VFPv3, VFPv4, Advanced SIMDv1

VPUSH<c> <list> <list> is consecutive 64-bit registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
single_regs = FALSE; d = UInt(D:Vd); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FSTMX".
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if VFPSmallRegisterBank() && (d+regs) > 16 then UNPREDICTABLE;
```

### Encoding T2/A2 VFPv2, VFPv3, VFPv4

VPUSH<c> <list> <list> is consecutive 32-bit registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	0	1	0	D	1	0	1	1	0	1	Vd	1	0	1	0	imm8										

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		1	1	0	1	0	D	1	0	1	1	0	1	Vd		1	0	1	0	imm8											

```
single_regs = TRUE; d = UInt(Vd:D);
imm32 = ZeroExtend(imm8:'00', 32); regs = UInt(imm8);
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VPUSH* on page AppxA-4753.

### FSTMX

Encoding T1/A1 behaves as described by the pseudocode if imm8 is odd. However, there is no UAL syntax for such encodings and ARM deprecates their use. For more information, see *FLDMX, FSTMX* on page F8-3080.

## Assembler syntax

VPUSH{<c>}{<q>}{.<size>} <list>

where:

- <c>, <q> See [Standard assembler syntax fields on page F2-2415](#).
- <size> An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers in <list>.
- <list> The extension registers to be stored, as a list of consecutively numbered doubleword (encoding T1/A1) or singleword (encoding T2/A2) registers, separated by commas and surrounded by brackets. It is encoded in the instruction by setting D and Vd to specify the first register in the list, and imm8 to twice the number of registers in the list (encoding T1/A1), or the number of registers in the list (encoding T2/A2). <list> must contain at least one register, and not more than sixteen.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE); NullCheckIfThumbEE(13);
    address = SP - imm32;
    SP = SP - imm32;
    if single_regs then
        for r = 0 to regs-1
            MemA[address,4] = S[d+r]; address = address+4;
    else
        for r = 0 to regs-1
            // Store as two word-aligned words in the correct order for current endianness.
            MemA[address,4] = if BigEndian() then D[d+r]<63:32> else D[d+r]<31:0>;
            MemA[address+4,4] = if BigEndian() then D[d+r]<31:0> else D[d+r]<63:32>;
            address = address+8;
```

## F8.1.111 VQABS

Vector Saturating Absolute takes the absolute value of each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, `FPSCR.QC`, is set if saturation occurs. For details see [Pseudocode details of saturation on page E1-2293](#).

Depending on settings in the `CPACR`, `NSACR`, and `HCPTR` registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

    for r = 0 to regs-1
        for e = 0 to elements-1
            result = Abs(SInt(Elem[D[m+r],e,esize]));
            (Elem[D[d+r],e,esize], sat) = SignedSatQ(result, esize);
            if sat then FPSR.QC = '1';
```

## F8.1.112 VQADD

Vector Saturating Add adds the values of corresponding elements of two vectors, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, `FPSCR.QC`, is set if saturation occurs. For details see [Pseudocode details of saturation on page E1-2293](#).

Depending on settings in the `CPACR`, `NSACR`, and `HCPTR` registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

            if sat then FPSR.QC = '1';
  
```

### F8.1.113 VQDMLAL, VQDMLSL

Vector Saturating Doubling Multiply Accumulate Long multiplies corresponding elements in two doubleword vectors, doubles the products, and accumulates the results into the elements of a quadword vector.

Vector Saturating Doubling Multiply Subtract Long multiplies corresponding elements in two doubleword vectors, subtracts double the products from corresponding elements of a quadword vector, and places the results in the same quadword vector.

In both instructions, the second operand can be a scalar instead of a vector. For more information about scalars see [Advanced SIMD scalars on page F5-2498](#).

If any of the results overflow, they are saturated. The cumulative saturation bit, `FPSCR.QC`, is set if saturation occurs. For details see [Pseudocode details of saturation on page E1-2293](#).

Depending on settings in the `CPACR`, `NSACR`, and `HCPTR` registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.         Elem[Q[d>>1],e,2*esize] = product;  
        if sat then FPSR.QC = '1';
```

## F8.1.116 VQMOVN, VQMOVUN

Vector Saturating Move and Narrow copies each element of the operand vector to the corresponding element of the destination vector.

The operand is a quadword vector. The elements can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result is a doubleword vector. The elements are half the length of the operand vector elements. If the operand is unsigned, the results are unsigned. If the operand is signed, the results can be signed or unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, `FPSCR.QC`, is set if saturation occurs. For details see [Pseudocode details of saturation on page E1-2293](#).

Depending on settings in the `CPACR`, `NSACR`, and `HCPTR` registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

        (Elem[D[d], e, esize], sat) = SatQ(operand, esize, dest_unsigned);
        if sat then FPSR.QC = '1';
```

## F8.1.117 VQNEG

Vector Saturating Negate negates each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, `FPSCR.QC`, is set if saturation occurs. For details see [Pseudocode details of saturation on page E1-2293](#).

Depending on settings in the `CPACR`, `NSACR`, and `HCPTR` registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

            if sat then FPSR.QC = '1';
```

## F8.1.118 VQRDMULH

Vector Saturating Rounding Doubling Multiply Returning High Half multiplies corresponding elements in two vectors, doubles the results, and places the most significant half of the final results in the destination vector. The results are rounded. For truncated results see [VQDMULH](#) on page F8-3278.

The second operand can be a scalar instead of a vector. For more information about scalars see [Advanced SIMD scalars](#) on page F5-2498.

If any of the results overflow, they are saturated. The cumulative saturation bit, `FPSCR.QC`, is set if saturation occurs. For details see [Pseudocode details of saturation](#) on page E1-2293.

Depending on settings in the `CPACR`, `NSACR`, and `HCPTR` registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality](#) on page G1-3498 summarizes these controls.

            Elem[D[d+r],e,esize] = result;
            if sat then FPSR.QC = '1';
  
```

## F8.1.119 VQRSHL

Vector Saturating Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

For truncated results see [VQSHL \(register\)](#) on page F8-3292.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, `FPSCR.QC`, is set if saturation occurs. For details see [Pseudocode details of saturation](#) on page E1-2293.

Depending on settings in the `CPACR`, `NSACR`, and `HCPTR` registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality](#) on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution](#) on page F2-2416.

            Elem[D[d+r],e,esize] = result;
            if sat then FPSR.QC = '1';
  
```

## F8.1.120 VQRSHRN, VQRSHRUN

Vector Saturating Rounding Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the rounded results in a doubleword vector.

For truncated results, see [VQSHRN, VQSHRUN on page F8-3296](#).

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode details of saturation on page E1-2293](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

## Assembler syntax

VQSHL{U}{<c>}{<q>}.<type><size> {<Qd>}, <Qm>, #<imm> Encoded as Q = 1  
 VQSHL{U}{<c>}{<q>}.<type><size> {<Dd>}, <Dm>, #<imm> Encoded as Q = 0

where:

U If present, specifies that the results are unsigned, although the operands are signed.

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VQSHL or VQSHLU instruction must be unconditional. ARM strongly recommends that a T32 VQSHL or VQSHLU instruction is unconditional, see [Conditional execution on page F2-2416](#).

<type> The data type for the elements of the vectors. It must be one of:

S Signed. Encoded as:

- U = 0, op = 1, for VQSHL.
- U = 1, op = 0, for VQSHLU.

U Unsigned:

- Encoded as U = 1, op = 1, for VQSHL.
- Not available for VQSHLU.

<size> The data size for the elements of the vectors. It must be one of:

8 Encoded as L = 0, imm6<5:3> = 0b001. <imm> is encoded in imm6<2:0>.

16 Encoded as L = 0, imm6<5:4> = 0b01. <imm> is encoded in imm6<3:0>.

32 Encoded as L = 0, imm6<5> = 0b1. <imm> is encoded in imm6<4:0>.

64 Encoded as L = 1. <imm> is encoded in imm6<5:0>.

<Qd>, <Qm> The destination vector, and the operand vector, for a quadword operation.

<Dd>, <Dm> The destination vector, and the operand vector, for a doubleword operation.

<imm> The immediate value, in the range 0 to <size>-1. See the description of <size> for how <imm> is encoded.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            operand = Int(Elem[D[m+r],e,esize], src_unsigned);
            (result, sat) = SatQ(operand << shift_amount, esize, dest_unsigned);
            Elem[D[d+r],e,esize] = result;
            if sat then FPSR.QC = '1';
  
```

### F8.1.123 VQSHRN, VQSHRUN

Vector Saturating Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the truncated results in a doubleword vector.

For rounded results, see [VQRSHRN, VQRSHRUN on page F8-3290](#).

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode details of saturation on page E1-2293](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

VQSHRUN.I<size> <Dd>, <Qm>, #0 is a synonym for VQMOVUN.I<size> <Dd>, <Qm>

## F8.1.124 VQSUB

Vector Saturating Subtract subtracts the elements of the second operand vector from the corresponding elements of the first operand vector, and places the results in the destination vector. Signed and unsigned operations are distinct.

The operand and result elements must all be the same type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

If any of the results overflow, they are saturated. The cumulative saturation bit, `FPSCR.QC`, is set if saturation occurs. For details see [Pseudocode details of saturation on page E1-2293](#).

Depending on settings in the `CPACR`, `NSACR`, and `HCPTR` registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

### F8.1.128 VREV16, VREV32, VREV64

VREV16 (Vector Reverse in halfwords) reverses the order of 8-bit elements in each halfword of the vector, and places the result in the corresponding destination vector.

VREV32 (Vector Reverse in words) reverses the order of 8-bit or 16-bit elements in each word of the vector, and places the result in the corresponding destination vector.

VREV64 (Vector Reverse in doublewords) reverses the order of 8-bit, 16-bit, or 32-bit elements in each doubleword of the vector, and places the result in the corresponding destination vector.

There is no distinction between data types, other than size.

Figure F8-6 shows two examples of the operation of VREV.

Figure F8-6 VREV operation examples

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

if UInt(op)+UInt(size) >= 3 then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
esize = 8 << UInt(size); elements = 64 DIV esize;
groupsize = (1 << (3-UInt(op)-UInt(size))); // elements per reversing group: 2, 4 or 8
reverse_mask = (groupsize-1)<size-1:0>; // EORing mask used for index calculations
d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
    
```

## Assembler syntax

VREV<n>{<c>}{<q>}.<size> <Qd>, <Qm> Encoded as Q = 1  
 VREV<n>{<c>}{<q>}.<size> <Dd>, <Dm> Encoded as Q = 0

where:

<n> The size of the regions in which the vector elements are reversed. It must be one of:  
 16 Encoded as op = 0b10.  
 32 Encoded as op = 0b01.  
 64 Encoded as op = 0b00.

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VREV instruction must be unconditional. ARM strongly recommends that a T32 VREV instruction is unconditional, see [Conditional execution on page F2-2416](#).

<size> The size of the vector elements. It must be one of:  
 8 Encoded as size = 0b00.  
 16 Encoded as size = 0b01.  
 32 Encoded as size = 0b10.  
 <size> must specify a smaller size than <n>.

<Qd>, <Qm> The destination vector and the operand vector, for a quadword operation.

<Dd>, <Dm> The destination vector and the operand vector, for a doubleword operation.

If op + size >= 3, the instruction is reserved.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(64) dest;

    for r = 0 to regs-1
        for e = 0 to elements-1
            // Calculate destination element index by bitwise EOR on source element index:
            e_bits = e<size-1:0>; d_bits = e_bits EOR reverse_mask; d = UInt(d_bits);
            Elem[dest,d,esize] = Elem[D[m+r],e,esize];
        D[d+r] = dest;
```

## F8.1.129 VRHADD

Vector Rounding Halving Add adds corresponding elements in two vectors of integers, shifts each result right one bit, and places the final results in the destination vector.

The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The results of the halving operations are rounded. For truncated results see [VHADD](#), [VHSUB](#) on page F8-3172.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

[Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

      result = op1 + op2 + 1;
      Elem[D[d+r],e,esize] = result<esize:1>;
```

### F8.1.130 VRINTA, VRINTN, VRINTP, VRINTM (Advanced SIMD)

These instructions round a floating-point value to an integral floating-point value of the same size. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

These instructions use the following rounding modes:

- VRINTA: Round to Nearest with Ties to Away.
- VRINTN: Round to Nearest with Ties to Even.
- VRINTP: Round Toward +Infinity.
- VRINTM: Round towards -Infinity.

```

### F8.1.132 VRINTX (Advanced SIMD)

This instruction rounds a floating-point value to an integral floating-point value of the same size. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

VRINTX uses the Round to Nearest with Ties to Even rounding mode, and raises the Inexact exception when the result value is not numerically equal to the input value.

    if dp_operation then
        D[d] = FPRoundInt(D[m], FPSCR, rounding, exact);
    else
        S[d] = FPRoundInt(S[m], FPSCR, rounding, exact);
```

## F8.1.136 VRSHL

Vector Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see [VSHL \(register\)](#) on page F8-3340.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

[Summary of access controls for Advanced SIMD functionality](#) on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution](#) on page F2-2416.

```

## Assembler syntax

VRSHL{<c>}{<q>}.<type><size> {<Qd>}, <Qm>, <Qn> Encoded as Q = 1  
 VRSHL{<c>}{<q>}.<type><size> {<Dd>}, <Dm>, <Dn> Encoded as Q = 0

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VRSHL instruction must be unconditional. ARM strongly recommends that a T32 VRSHL instruction is unconditional, see [Conditional execution on page F2-2416](#).

<type> The data type for the elements of the vectors. It must be one of:  
 S Signed, encoded as U = 0.  
 U Unsigned, encoded as U = 1.  
 Together with the <size> field, this indicates the data type and size of the first operand and the result.

<size> The data size for the elements of the vectors. It must be one of:  
 8 Encoded as size = 0b00.  
 16 Encoded as size = 0b01.  
 32 Encoded as size = 0b10.  
 64 Encoded as size = 0b11.

<Qd>, <Qm>, <Qn> The destination vector and the operand vectors, for a quadword operation.

<Dd>, <Dm>, <Dn> The destination vector and the operand vectors, for a doubleword operation.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            shift = SInt(Elem[D[n+r],e,esize]<7:0>);
            round_const = 1 << (-shift-1); // 0 for left shift, 2^(n-1) for right shift
            result = (Int(Elem[D[m+r],e,esize], unsigned) + round_const) << shift;
            Elem[D[d+r],e,esize] = result<esize-1:0>;
  
```

## F8.1.137 VRSHR

Vector Rounding Shift Right takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector. For truncated results, see [VSHR](#) on page F8-3344.

The operand and result elements must be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

[Summary of access controls for Advanced SIMD functionality](#) on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution](#) on page F2-2416.

<dt> The data type for the elements of the operands. It must be one of:  
I16 Encoded as size = 0b00.  
I32 Encoded as size = 0b01.  
I64 Encoded as size = 0b10.

<Dd>, <Qn>, <Qm> The destination vector and the operand vectors.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    round_const = 1 << (esize-1);
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] - Elem[Qin[m>>1],e,2*esize] + round_const;
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

### F8.1.143 VSEL

Floating-point selection allows the destination register to take the value in either one or the other source register according to the condition codes in the [APSR](#).

If VSEL generates an exception, it is regarded as unconditional for the purpose of reporting the condition field in the Exception Syndrome register.

VSEL cannot be made conditional using the IT mechanism in T32.

else  
    S[d] = if ConditionPassed() then S[n] else S[m];
```

### F8.1.144 VSHL (immediate)

Vector Shift Left (immediate) takes each element in a vector of integers, left shifts them by an immediate value, and places the results in the destination vector.

Bits shifted out of the left of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = LSL(Elem[D[m+r],e,esize], shift_amount);
  
```

## F8.1.145 VSHL (register)

Vector Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift.

———— **Note** —————

For a rounding shift, see [VRSHL](#) on page F8-3322.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

            result = Int(Elem[D[m+r],e,esize], unsigned) << shift;
            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

## F8.1.146 VSHLL

Vector Shift Left Long takes each element in a doubleword vector, left shifts them by an immediate value, and places the results in a quadword vector.

The operand elements can be:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit untyped integers, maximum shift only.

The result elements are twice the length of the operand elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

    for e = 0 to elements-1
        result = LSR(Elem[Qin[m]>>1], e, 2*esize), shift_amount);
        Elem[D[d], e, esize] = result<size-1:0>;
```

## Pseudo-instructions

VSHRN.I<size> <Dd>, <Qm>, #0 is a synonym for VMOVN.I<size> <Dd>, <Qm>

For details see [VMOVN on page F8-3230](#).

## F8.1.149 VSLI

Vector Shift Left and Insert takes each element in the operand vector, left shifts them by an immediate value, and inserts the results in the destination vector. Bits shifted out of the left of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit. There is no distinction between data types.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

[Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

### Encoding T1/A1 Advanced SIMDv1

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2415.  
<Dd>, <Dm> The destination vector and the operand vector, for a double-precision operation.  
<Sd>, <Sm> The destination vector and the operand vector, for a single-precision operation.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEEnabled(TRUE);
    if dp_operation then
        D[d] = FPSqrt(D[m], StandardFPSCRValue());
    else
        S[d] = FPSqrt(S[m], StandardFPSCRValue());
```

## F8.1.151 VSRA

Vector Shift Right and Accumulate takes each element in a vector, right shifts them by an immediate value, and accumulates the truncated results into the destination vector. For rounded results, see [VRSRA on page F8-3332](#).

The operand and result elements must all be the same type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

[Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

 VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm> Rm cannot be 0b11x1

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VST1 instruction must be unconditional. ARM strongly recommends that a T32 VST1 instruction is unconditional, see [Conditional execution on page F2-2416](#).

<size> The data size. It must be one of:  
 8 Encoded as size = 0b00.  
 16 Encoded as size = 0b01.  
 32 Encoded as size = 0b10.

<list> The register containing the element to store. It must be {<Dd[x]>}. The register Dd is encoded in D:Vd

<Rn> Contains the base address for the access.

<align> The alignment. It can be one of:  
 16 2-byte alignment, available only if <size> is 16.  
 32 4-byte alignment, available only if <size> is 32.  
**omitted** Standard alignment, see [Unaligned data access on page E2-2341](#).  
 : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode on page F5-2517](#).

! If present, specifies writeback.

<Rm> Contains an address offset applied after the access.

For more information about <Rn>, !, and <Rm>, see [Advanced SIMD addressing mode on page F5-2517](#).

[Table F8-6](#) shows the encoding of index and alignment for different <size> values.

**Table F8-6 Encoding of index and alignment**

	<size> == 8	<size> == 16	<size> == 32
Index	index_align[3:1] = x	index_align[3:2] = x	index_align[3] = x
<align> omitted	index_align[0] = 0	index_align[1:0] = '00'	index_align[2:0] = '000'
<align> == 16	-	index_align[1:0] = '01'	-
<align> == 32	-	-	index_align[2:0] = '011'

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled(); NullCheckIfThumbEE(n);
    address = R[n]; if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else ebytes);
    MemU[address,ebytes] = Elem[D[d],index];
  
```

## F8.1.155 VST2 (multiple 2-element structures)

This instruction stores multiple 2-element structures from two or four registers to memory, with interleaving. For more information, see *Element and structure load/store instructions* on page F1-2398. Every element of each register is saved. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2517.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page F2-2416.

## Assembler syntax

VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}] Encoded as Rm = 0b1111  
 VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]! Encoded as Rm = 0b1101  
 VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm> Rm cannot be 0b11x1

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VST4 instruction must be unconditional. ARM strongly recommends that a T32 VST4 instruction is unconditional, see [Conditional execution on page F2-2416](#).

<size> The data size. It must be one of:  
 8 Encoded as size = 0b00.  
 16 Encoded as size = 0b01.  
 32 Encoded as size = 0b10.

<list> The list of registers to store. It must be one of:  
 {<Dd>, <Dd+1>, <Dd+2>, <Dd+3>}  
 Encoded as D:Vd = <Dd>, type = 0b0000.  
 {<Dd>, <Dd+2>, <Dd+4>, <Dd+6>}  
 Encoded as D:Vd = <Dd>, type = 0b0001.

<Rn> Contains the base address for the access.

<align> The alignment. It can be one of:  
 64 8-byte alignment, encoded as align = 0b01.  
 128 16-byte alignment, encoded as align = 0b10.  
 256 32-byte alignment, encoded as align = 0b11.  
**omitted** Standard alignment, see [Unaligned data access on page E2-2341](#). Encoded as align = 0b00.  
 : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode on page F5-2517](#).

! If present, specifies writeback.

<Rm> Contains an address offset applied after the access.

For more information about <Rn>, !, and <Rm>, see [Advanced SIMD addressing mode on page F5-2517](#).

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled(); NullCheckIfThumbEE(n);
    address = R[n]; if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 32);
    for e = 0 to elements-1
        MemU[address, ebytes] = Elem[D[d], e];
        MemU[address+ebytes, ebytes] = Elem[D[d2], e];
        MemU[address+2*ebytes, ebytes] = Elem[D[d3], e];
        MemU[address+3*ebytes, ebytes] = Elem[D[d4], e];
        address = address + 4*ebytes;
```

## F8.1.160 VST4 (single 4-element structure from one lane)

This instruction stores one 4-element structure to memory from corresponding elements of four registers. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2517.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page F2-2416.

### Assembler syntax

VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}] Encoded as Rm = 0b1111  
 VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]! Encoded as Rm = 0b1101  
 VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm> Rm cannot be 0b11x1

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2415. An A32 VST4 instruction must be unconditional. ARM strongly recommends that a T32 VST4 instruction is unconditional, see *Conditional execution* on page F2-2416.

<size> The data size. It must be one of:

8	Encoded as size = 0b00.
16	Encoded as size = 0b01.
32	Encoded as size = 0b10.

- <list> The registers containing the structure. Encoded with  $D:Vd = \langle Dd \rangle$ . It must be one of:  
 { $\langle Dd[x] \rangle$ ,  $\langle Dd+1[x] \rangle$ ,  $\langle Dd+2[x] \rangle$ ,  $\langle Dd+3[x] \rangle$ }  
 Single-spaced registers, see [Table F8-9](#).  
 { $\langle Dd[x] \rangle$ ,  $\langle Dd+2[x] \rangle$ ,  $\langle Dd+4[x] \rangle$ ,  $\langle Dd+6[x] \rangle$ }  
 Double-spaced registers, see [Table F8-9](#). This is not available if  $\langle \text{size} \rangle == 8$ .
- <Rn> The base address for the access.
- <align> The alignment. It can be:  
 32 4-byte alignment, available only if  $\langle \text{size} \rangle$  is 8.  
 64 8-byte alignment, available only if  $\langle \text{size} \rangle$  is 16 or 32.  
 128 16-byte alignment, available only if  $\langle \text{size} \rangle$  is 32.  
**omitted** Standard alignment, see [Unaligned data access on page E2-2341](#).  
 : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode on page F5-2517](#).
- ! If present, specifies writeback.
- <Rm> Contains an address offset applied after the access.

For more information about <Rn>, !, and <Rm>, see [Advanced SIMD addressing mode on page F5-2517](#).

**Table F8-9 Encoding of index, alignment, and register spacing**

	$\langle \text{size} \rangle == 8$	$\langle \text{size} \rangle == 16$	$\langle \text{size} \rangle == 32$
Index	$\text{index\_align}[3:1] = x$	$\text{index\_align}[3:2] = x$	$\text{index\_align}[3] = x$
Single-spacing	-	$\text{index\_align}[1] = 0$	$\text{index\_align}[2] = 0$
Double-spacing	-	$\text{index\_align}[1] = 1$	$\text{index\_align}[2] = 1$
<align> omitted	$\text{index\_align}[0] = 0$	$\text{index\_align}[0] = 0$	$\text{index\_align}[1:0] = '00'$
<align> == 32	$\text{index\_align}[0] = 1$	-	-
<align> == 64	-	$\text{index\_align}[0] = 1$	$\text{index\_align}[1:0] = '01'$
<align> == 128	-	-	$\text{index\_align}[1:0] = '10'$

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled(); NullCheckIfThumbEE(n);
    address = R[n]; if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 4*ebytes);
    MemU[address, ebytes] = Elem[D[d], index];
    MemU[address+ebytes, ebytes] = Elem[D[d2], index];
    MemU[address+2*ebytes, ebytes] = Elem[D[d3], index];
    MemU[address+3*ebytes, ebytes] = Elem[D[d4], index];
    
```

## F8.1.161 VSTM

Vector Store Multiple stores multiple extension registers to consecutive memory locations using an address from a general-purpose register.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality on page G1-3496* and *Summary of access controls for Advanced SIMD functionality on page G1-3498* summarize these controls.

### Encoding T1/A1 VFPv2, VFPv3, VFPv4, Advanced SIMDv1

VSTM{mode}<c> <Rn>{!}, <list> <list> is consecutive 64-bit registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FSTMX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if VFPSmallRegisterBank() && (d+regs) > 16 then UNPREDICTABLE;
    
```

### Encoding T2/A2 VFPv2, VFPv3, VFPv4

VSTM{mode}<c> <Rn>{!}, <list> <list> is consecutive 32-bit registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	0	P	U	D	W	0	Rn				Vd	1	0	1	0	imm8										

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1	1	0	P	U	D	W	0	Rn				Vd	1	0	1	0	imm8										

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && U == '0' && W == '1' && Rn == '1101' then SEE VPUSH;
if P == '1' && W == '0' then SEE VSTR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = TRUE; add = (U == '1'); wback = (W == '1'); d = UInt(Vd:D); n = UInt(Rn);
imm32 = ZeroExtend(imm8:'00', 32); regs = UInt(imm8);
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
    
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VSTM* on page AppxA-4752.

**Related encodings** See *64-bit transfers between general-purpose and extension registers* on page F5-2519.

**FSTMX** Encoding T1/A1 behaves as described by the pseudocode if imm8 is odd. However, there is no UAL syntax for such encodings and ARM deprecates their use. For more information, see *FLDMX, FSTMX* on page F8-3080.

## Assembler syntax

VSTM{<mode>}{<C>}{<q>}{.<size>} <Rn>{!}, <list>

where:

<mode>	The addressing mode:
IA	Increment After. The consecutive addresses start at the address specified in <Rn>. This is the default and can be omitted. Encoded as P = 0, U = 1.
DB	Decrement Before. The consecutive addresses end just before the address specified in <Rn>. Encoded as P = 1, U = 0.
<C>, <q>	See <i>Standard assembler syntax fields</i> on page F2-2415.
<size>	An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers in <list>.
<Rn>	The base register. The SP can be used. In the A32 instruction set, if ! is not specified the PC can be used. However, ARM deprecates use of the PC.
!	Causes the instruction to write a modified value back to <Rn>. Required if <mode> == DB. Encoded as W = 1. If ! is omitted, the instruction does not change <Rn> in this way. Encoded as W = 0.
<list>	The extension registers to be stored, as a list of consecutively numbered doubleword (encoding T1/A1) or singleword (encoding T2/A2) registers, separated by commas and surrounded by brackets. It is encoded in the instruction by setting D and Vd to specify the first register in the list, and imm8 to twice the number of registers in the list (encoding T1/A1) or the number of registers (encoding T2/A2). <list> must contain at least one register. If it contains doubleword registers it must not contain more than 16 registers.

## Operation

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE); NullCheckIfThumbEE(n);
    address = if add then R[n] else R[n]-imm32;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            MemA[address,4] = S[d+r]; address = address+4;
        else
            // Store as two word-aligned words in the correct order for current endianness.
            MemA[address,4] = if BigEndian() then D[d+r]<63:32> else D[d+r]<31:0>;
            MemA[address+4,4] = if BigEndian() then D[d+r]<31:0> else D[d+r]<63:32>;
            address = address+8;
  
```

## F8.1.162 VSTR

This instruction stores a single extension register to memory, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of general controls of CP10 and CP11 functionality on page G1-3496](#) and [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarize these controls.

### Encoding T1/A1 VFPv2, VFPv3, VFPv4, Advanced SIMDv1

```
single_reg = FALSE; add = (U == '1'); imm32 = ZeroExtend(imm8:'00', 32);
d = UInt(D:Vd); n = UInt(Rn);
if n == 15 && CurrentInstrSet() != InstrSet_A32 then UNPREDICTABLE;
```

### Encoding T2/A2 VFPv2, VFPv3, VFPv4

VSTR<c> <Sd>, [<Rn>{, #+/-<imm>}]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	0	1	U	D	0	0	Rn				Vd		1	0	1	0	imm8									

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond		1	1	0	1	U	D	0	0	Rn				Vd		1	0	1	0	imm8											

```
single_reg = TRUE; add = (U == '1'); imm32 = ZeroExtend(imm8:'00', 32);
d = UInt(Vd:D); n = UInt(Rn);
if n == 15 && CurrentInstrSet() != InstrSet_A32 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#).

## Assembler syntax

VSTR{<C>}{<q>}{.64} <Dd>, [<Rn>{, #+/-<imm>}] Encoding T1/A1  
 VSTR{<C>}{<q>}{.32} <Sd>, [<Rn>{, #+/-<imm>}] Encoding T2/A2

where:

<C>, <q> See [Standard assembler syntax fields on page F2-2415](#).  
 .32, .64 Optional data size specifiers.  
 <Dd> The source register for a doubleword store.  
 <Sd> The source register for a singleword store.  
 <Rn> The base register. The SP can be used. In the A32 instruction set the PC can be used. However, ARM deprecates use of the PC.  
 +/- Is + or omitted if the immediate offset is to be added to the base register value (add == TRUE), or – if it is to be subtracted (add == FALSE). #0 and #-0 generate different instructions.  
 <imm> The immediate offset used for forming the address. Values are multiples of 4 in the range 0-1020. <imm> can be omitted, meaning an offset of +0.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE); NullCheckIfThumbEE(n);
    address = if add then (R[n] + imm32) else (R[n] - imm32);
    if single_reg then
        MemA[address,4] = S[d];
    else
        // Store as two word-aligned words in the correct order for current endianness.
        MemA[address,4] = if BigEndian() then D[d]<63:32> else D[d]<31:0>;
        MemA[address+4,4] = if BigEndian() then D[d]<31:0> else D[d]<63:32>;
```

### F8.1.163 VSUB (integer)

Vector Subtract subtracts the elements of one vector from the corresponding elements of another vector, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

[Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

#### Encoding T1/A1 Advanced SIMDv1

VSUB<c>.<dt> <Qd>, <Qn>, <Qm>

VSUB<c>.<dt> <Dd>, <Dn>, <Dm>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
```

## Assembler syntax

`VSUB{<c>}{<q>}.<dt> {<Qd>}, <Qn>, <Qm>`

`VSUB{<c>}{<q>}.<dt> {<Dd>}, <Dn>, <Dm>`

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 Advanced SIMD VSUB instruction must be unconditional. ARM strongly recommends that a T32 Advanced SIMD VSUB instruction is unconditional, see [Conditional execution on page F2-2416](#).

<dt> The data type for the elements of the vectors. It must be one of:

I8 Encoded as size = 0b00.

I16 Encoded as size = 0b01.

I32 Encoded as size = 0b10.

I64 Encoded as size = 0b11.

<Qd>, <Qn>, <Qm> The destination vector and the operand vectors, for a quadword operation.

<Dd>, <Dn>, <Dm> The destination vector and the operand vectors, for a doubleword operation.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = Elem[D[n+r],e,esize] - Elem[D[m+r],e,esize];
```

## F8.1.164 VSUB (floating-point)

Vector Subtract subtracts the elements of one vector from the corresponding elements of another vector, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality on page G1-3496* and *Summary of access controls for Advanced SIMD functionality on page G1-3498* summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution on page F2-2416*.

        if dp_operation then
            D[d] = FPSub(D[n], D[m], FPSCR);
        else
            S[d] = FPSub(S[n], S[m], FPSCR);
  
```

## F8.1.165 VSUBHN

Vector Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector, takes the most significant half of each result, and places the final results in a doubleword vector. The results are truncated. For rounded results, see [VRSUBHN](#) on page F8-3334.

There is no distinction between signed and unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality](#) on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution](#) on page F2-2416.

## Assembler syntax

VSUBHN{<c>}{<q>}.<dt> <Dd>, <Qn>, <Qm>

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VSUBHN instruction must be unconditional. ARM strongly recommends that a T32 VSUBHN instruction is unconditional, see [Conditional execution on page F2-2416](#).

<dt> The data type for the elements of the operands. It must be one of:  
I16 Encoded as size = 0b00.  
I32 Encoded as size = 0b01.  
I64 Encoded as size = 0b10.

<Dd>, <Qn>, <Qm> The destination vector, the first operand vector, and the second operand vector.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] - Elem[Qin[m>>1],e,2*esize];
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

## F8.1.166 VSUBL, VSUBW

Vector Subtract Long subtracts the elements of one doubleword vector from the corresponding elements of another doubleword vector, and places the results in a quadword vector. Before subtracting, it sign-extends or zero-extends the elements of both operands.

Vector Subtract Wide subtracts the elements of a doubleword vector from the corresponding elements of a quadword vector, and places the results in another quadword vector. Before subtracting, it sign-extends or zero-extends the elements of the doubleword operand.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
    
```

## Assembler syntax

VSWP{<c>}{<q>}{.<dt>} <Qd>, <Qm> Encoded as Q = 1, size = 0b00  
VSWP{<c>}{<q>}{.<dt>} <Dd>, <Dm> Encoded as Q = 0, size = 0b00

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VSWP instruction must be unconditional. ARM strongly recommends that a T32 VSWP instruction is unconditional, see [Conditional execution on page F2-2416](#).

<dt> An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd>, <Qm> The vectors for a quadword operation.

<Dd>, <Dm> The vectors for a doubleword operation.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        if d == m then
            D[d+r] = bits(64) UNKNOWN;
        else
            D[d+r] = Din[m+r];
            D[m+r] = Din[d+r];
```

## F8.1.168 VTBL, VTBX

Vector Table Lookup uses byte indexes in a control vector to look up byte values in a table and generate a new vector. Indexes out of range return 0.

Vector Table Extension works in the same way, except that indexes out of range leave the destination element unchanged.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

### Encoding T1/A1 Advanced SIMDv1

is_vtbl = (op == '0'); length = UInt(len)+1;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
if n+length > 32 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix A Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VTBL, VTBX on page AppxA-4753](#).

## Assembler syntax

V<op>{<c>}{<q>}.8 <Dd>, <list>, <Dm>

where:

- <op>           The operation. It must be one of:  
           TBL           Vector Table Lookup. Encoded as op = 0.  
           VBX           Vector Table Extension. Encoded as op = 1.
- <c>, <q>       See [Standard assembler syntax fields on page F2-2415](#). An A32 VTBL or VTBX instruction must be unconditional. ARM strongly recommends that a T32 VTBL or VTBX instruction is unconditional, see [Conditional execution on page F2-2416](#).
- <Dd>           The destination vector.
- <list>         The vectors containing the table. It must be one of:  
           {<Dn>}           Encoded as len = 0b00.  
           {<Dn>, <Dn+1>}   Encoded as len = 0b01.  
           {<Dn>, <Dn+1>, <Dn+2>} Encoded as len = 0b10.  
           {<Dn>, <Dn+1>, <Dn+2>, <Dn+3>}  
                               Encoded as len = 0b11.
- <Dm>           The index vector.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();

    // Create 256-bit = 32-byte table variable, with zeros in entries that will not be used.
    table3 = if length == 4 then D[n+3] else Zeros(64);
    table2 = if length >= 3 then D[n+2] else Zeros(64);
    table1 = if length >= 2 then D[n+1] else Zeros(64);
    table = table3 : table2 : table1 : D[n];

    for i = 0 to 7
        index = UInt(Elem[D[m],i,8]);
        if index < 8*length then
            Elem[D[d],i,8] = Elem[table,index,8];
        else
            if is_vtbl then
                Elem[D[d],i,8] = Zeros(8);
            // else Elem[D[d],i,8] unchanged
```

## F8.1.169 VTRN

Vector Transpose treats the elements of its operand vectors as elements of  $2 \times 2$  matrices, and transposes the matrices.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

Figure F8-7 shows the operation of doubleword VTRN. Quadword VTRN performs the same operation as doubleword VTRN twice, once on the upper halves of the quadword vectors, and once on the lower halves

Figure F8-7 VTRN doubleword operation

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode.

Summary of access controls for Advanced SIMD functionality on page G1-3498 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see Conditional execution on page F2-2416.

d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
    
```

## Assembler syntax

VTRN{<c>}{<q>}.<size> <Qd>, <Qm> Encoded as Q = 1  
 VTRN{<c>}{<q>}.<size> <Dd>, <Dm> Encoded as Q = 0

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VTRN instruction must be unconditional. ARM strongly recommends that a T32 VTRN instruction is unconditional, see [Conditional execution on page F2-2416](#).

<size> The data size for the elements of the vectors. It must be one of:

8 Encoded as size = 0b00.  
 16 Encoded as size = 0b01.  
 32 Encoded as size = 0b10.

<Qd>, <Qm> The destination vector, and the operand vector, for a quadword operation.

<Dd>, <Dm> The destination vector, and the operand vector, for a doubleword operation.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    h = elements DIV 2;

    for r = 0 to regs-1
        if d == m then
            D[d+r] = bits(64) UNKNOWN;
        else
            for e = 0 to h-1
                Elem[D[d+r],2*e+1,esize] = Elem[Din[m+r],2*e,esize];
                Elem[D[m+r],2*e,esize] = Elem[Din[d+r],2*e+1,esize];
```

## F8.1.170 VTST

Vector Test Bits takes each element in a vector, and bitwise ANDs it with the corresponding element of a second vector. If the result is not zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit fields.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

esize = 8 << UInt(size); elements = 64 DIV esize;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
    
```

## Assembler syntax

VTST{<c>}{<q>}.<size> {<Qd>}, <Qn>, <Qm> Encoded as Q = 1  
VTST{<c>}{<q>}.<size> {<Dd>}, <Dn>, <Dm> Encoded as Q = 0

where:

<c>, <q> See [Standard assembler syntax fields on page F2-2415](#). An A32 VTST instruction must be unconditional. ARM strongly recommends that a T32 VTST instruction is unconditional, see [Conditional execution on page F2-2416](#).

<size> The data size for the elements of the operands. It must be one of:  
8 Encoded as size = 0b00.  
16 Encoded as size = 0b01.  
32 Encoded as size = 0b10.

<Qd>, <Qn>, <Qm> The destination vector and the operand vectors, for a quadword operation.

<Dd>, <Dn>, <Dm> The destination vector and the operand vectors, for a doubleword operation.

## Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            if !IsZero(Elem[D[n+r],e,esize] AND Elem[D[m+r],e,esize]) then
                Elem[D[d+r],e,esize] = Ones(esize);
            else
                Elem[D[d+r],e,esize] = Zeros(esize);
```

## F8.1.171 VUZP

Vector Unzip de-interleaves the elements of two vectors. See [Table F8-10](#) and [Table F8-11](#) for examples of the operation.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. [Summary of access controls for Advanced SIMD functionality on page G1-3498](#) summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see [Conditional execution on page F2-2416](#).

# Part G

## **The AArch32 System Level Architecture**

# Chapter G1

## The AArch32 System Level Programmers' Model

This chapter gives a system level description of the programmers' model for execution in AArch32 state. It contains the following sections:

- *About the AArch32 System level programmers' model* on page G1-3400.
- *Exception levels* on page G1-3401.
- *Exception terminology* on page G1-3402.
- *Execution state* on page G1-3404.
- *Instruction Set state* on page G1-3406.
- *Debug state* on page G1-3406.
- *Security state* on page G1-3407.
- *Virtualization* on page G1-3410.
- *AArch32 PE modes, general-purpose registers, and the PC* on page G1-3412.
- *Instruction set states* on page G1-3429.
- *Handling exceptions that are taken to an Exception level using AArch32* on page G1-3431.
- *Asynchronous exception behavior for exceptions taken from AArch32 state* on page G1-3465.
- *AArch32 state exception descriptions* on page G1-3475.
- *The conceptual coprocessor interface and system control* on page G1-3492.
- *Advanced SIMD and floating-point support* on page G1-3494.
- *AArch32 control of traps to the hypervisor* on page G1-3503.

## G1.1 About the AArch32 System level programmers' model

An application programmer has only a restricted view of the system. The System level programmers' model supports this application level view of the system, and includes features required for one or both of an operating system (OS) and a hypervisor to provide the programming environment seen by an application. This chapter describes the System level programmers' model when executing at EL1 or higher in an Exception level that is using AArch32.

The system level programmers' model includes all of the system features required to support operating systems and to handle hardware events.

The sections listed below give a system level introduction to the basic concepts of the ARM architecture AArch32 state, and the terminology used for describing the architecture when executing in this state:

- [Exception levels on page G1-3401.](#)
- [Exception terminology on page G1-3402.](#)
- [Execution state on page G1-3404.](#)
- [Instruction Set state on page G1-3406.](#)
- [Debug state on page G1-3406.](#)
- [Security state on page G1-3407.](#)
- [Virtualization on page G1-3410.](#)

The rest of this chapter describes the system level programmers' model when executing in AArch32 state.

The other chapters in this part describe:

- The memory system architecture, as seen when executing in an Exception level that is using AArch32:
    - [Chapter G2 The AArch32 System Level Memory Model](#) describes the general features of the ARMv8 memory model, when executing in AArch32 state, that are not visible at the application level.
- **Note** —————
- [Chapter E2 The AArch32 Application Level Memory Model](#) describes the application level view of the memory model.
- 
- [Chapter G3 The AArch32 Virtual Memory System Architecture](#) describes the Virtual Memory System Architecture (VMSA) used in AArch32 state.
- The AArch32 System Registers, see [Chapter G4 AArch32 System Register Descriptions](#).

———— **Note** —————

The T32 and A32 instruction sets include instructions that provide system level functionality, such as returning from an exception. See [Alphabetical list of system instructions on page F7-3033](#).

## G1.2 Exception levels

The ARMv8-A architecture defines a set of Exception levels, EL0 to EL3, where:

- If EL $n$  is the Exception level, increased values of  $n$  indicate increased software execution privilege.
- Execution at EL0 is called *unprivileged execution*.
- EL2 provides support for virtualization of Non-secure operation.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

———— **Note** —————

A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

[Supported configurations on page D1-1554](#) provides information on implementations.

When executing in AArch32 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the *target Exception level* of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the system control registers.

An exception cannot target EL0.

Exception levels exist within *Security states*. [The ARMv8-A security model on page G1-3407](#) describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.
- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then because EL3 is only implemented in Secure state, execution at EL3 can access all resources available at all Exception levels, for both Security states.

Each exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see [Chapter G3 The AArch32 Virtual Memory System Architecture](#).

### G1.2.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

<b>EL0</b>	Applications.
<b>EL1</b>	OS kernel and associated functions that are typically described as <i>privileged</i> .
<b>EL2</b>	Hypervisor.
<b>EL3</b>	Secure monitor.

## G1.3 Exception terminology

The following subsections define the terms used when describing exceptions:

- [Terminology for taking an exception.](#)
- [Terminology for returning from an exception.](#)
- [Exception levels.](#)
- [Definition of a precise exception.](#)
- [Definitions of synchronous and asynchronous exceptions on page G1-3403.](#)

### G1.3.1 Terminology for taking an exception

An exception is *generated* when the PE first responds to an exceptional condition. The PE state at this time is the state the exception is *taken from*. The PE state immediately after taking the exception is the state the exception is *taken to*.

### G1.3.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction. The PE state when an exception return instruction is committed for execution is the state the exception *returns from*. The PE state immediately after the execution of that instruction is the state the exception *returns to*.

### G1.3.3 Exception levels

An Exception level,  $EL_n$ , with a larger value of  $n$  than another Exception level, is described as being a *higher* Exception level than the other Exception level. For example,  $EL_3$  is a higher Exception level than  $EL_1$ .

An Exception level with a smaller value of  $n$  than another Exception level is described as being a *lower* Exception level than the other Exception level. For example,  $EL_0$  is a lower Exception level than  $EL_1$ .

An Exception level is described as:

- *Using AArch64* when execution in that Exception level is in the AArch64 Execution state.
- *Using AArch32* when execution in that Exception level is in the AArch32 Execution state.

### G1.3.4 Definition of a precise exception

An exception is described as *precise* when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

Where a synchronous exception is generated as part of an instruction that performs more than one single-copy atomic memory access, such as the AArch32 LDM and STM instructions, the definition of precise permits that the values in registers or memory affected by those instructions can be UNKNOWN, provided that:

- The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
- The registers are not involved in the calculation of the memory address used by the instruction.

Other than the *Asynchronous Data Abort*, sometimes referred to as an *external interrupt*, all exceptions taken to AArch32 state are required to be precise.

For each occurrence of an Asynchronous Data Abort, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

———— **Note** —————

- For the definition of a single-copy atomic access, see [Single-copy atomicity on page E2-2346](#).
- Asynchronous Data Aborts are known as SError interrupts in AArch64 state.
- By definition, all synchronous aborts are precise.

### G1.3.5 Definitions of synchronous and asynchronous exceptions

An exception is described as *synchronous* if all of the following apply:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

An exception is described as *asynchronous* if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

For more information about exceptions, see [Handling exceptions that are taken to an Exception level using AArch32 on page G1-3431](#).

## G1.4 Execution state

The Execution states are:

**AArch64** The 64-bit Execution state.

**AArch32** The 32-bit Execution state. Operation in this state is compatible with ARMv7-A operation.

[Execution state on page A1-33](#) gives more information about them.

Exception levels *use* Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.
- The PE can change Execution states only either:
  - At reset.
  - On a change of Exception level.

---

**Note**

- [Typical Exception level usage model on page G1-3401](#) shows which Exception levels different software layers might typically use.
- [Supported configurations on page D1-1554](#) gives information on supported configurations of Exception levels and Execution states.

---

The interaction between the AArch64 and AArch32 Execution states is called *interprocessing*. [Interprocessing on page D1-1542](#) describes this.

### G1.4.1 About the AArch32 PE modes

AArch32 state provides a set of *PE modes* that support normal software execution and handle exceptions. The current mode determines the set of registers that are available, as described in [AArch32 general-purpose registers, and the PC on page G1-3418](#).

The AArch32 modes are:

- Monitor mode. This mode always executes at Secure EL3.
- Hyp mode. This mode always executes at Non-secure EL2.
- System, Supervisor, Abort, Undefined, IRQ and FIQ modes. The Exception level these modes execute at depends on the Security state, as described in [Security state on page G1-3407](#).
- User mode. This mode always executes at EL0.

---

**Note**

AArch64 state does not support modes. Modes are a concept that is specific to AArch32 state. Modes that execute at a particular Exception level are only implemented if that Exception level supports using AArch32.

---

For more information on modes see [AArch32 PE mode descriptions on page G1-3412](#).

The mode in use immediately before an exception is taken is described as the mode the exception is *taken from*. The mode that is used on taking the exception is described as the mode the exception is *taken to*.

All of the following define the mode that an exception is taken to:

- The type of exception.
- The mode the exception is taken from.

- Configuration settings defined at EL2 and EL3.

Monitor mode and Hyp mode can create system traps that cause exceptions to EL3 or EL2 respectively. There is an architected hierarchy where EL2 and EL3 configuration settings affect a common condition, for example interrupt routing. When no traps are enabled for a particular condition, the AArch32 mode an exception is taken to is called the *default mode* for that exception.

In AArch32 state, a number of different modes can exist at the same *Privilege level* (PL). All modes at a particular privilege level have the same access rights for accesses to memory and to System registers. The mapping of PE modes to Exception levels depends on the Security state, as described in [Security state on page G1-3407](#).

[Execution privilege, Exception levels, and AArch32 Privilege levels on page G3-3560](#) gives more information about the PE modes, their associated Privilege levels, and how these map onto the Exception levels.

## G1.5 Instruction Set state

In AArch32 state, the *Instruction Set state* determines the instruction set that the PE is executing. In an implementation that follows the ARM recommendations, the available Instruction Set states are:

**T32 state**      The PE is executing T32 instructions.

**A32 state**      The PE is executing A32 instructions.

———— **Note** —————

- In previous versions of the ARM architecture:
  - The T32 instruction set was called the Thumb instruction set.
  - The A32 instruction set was called the ARM instruction set.
- An ARMv8-A implementation can support the T32EE instruction set, previously called the ThumbEE instruction set. However, any support for T32EE is OPTIONAL and deprecated.

For more information, see [Instruction set state register, ISETSTATE](#) on page E1-2298.

## G1.6 Debug state

*Debug state* refers to the PE being halted for debug purposes, because a debug event has occurred when the PE is configured to Halting debug-mode.

When the PE is not in Debug state it is described as being in *Non-debug state*.

Except for part H of this manual, or where the context explicitly indicates otherwise, this manual describes PE behavior and instruction execution in Non-debug state. [Chapter H2 Debug State](#) describes the differences in Debug state.

## G1.7 Security state

The ARMv8-A architecture provides two Security states, each with an associated physical memory address space, as follows:

<b>Secure state</b>	When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space.
<b>Non-secure state</b>	When in this state, the PE: <ul style="list-style-type: none"> <li>• Can access only the Non-secure physical address space.</li> <li>• Cannot access the Secure system control resources.</li> </ul>

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see [About VMSAv8-32 on page G3-3562](#).

### G1.7.1 The ARMv8-A security model

The general principles of the ARMv8-A security model are:

- If the implementation includes EL3 then it has two Security states, Secure and Non-secure, and:
  - EL3 exists only in Secure state.
  - A change from Non-secure state to Secure state can only occur on taking an exception to EL3.
  - A change from Secure state to Non-secure state can only occur on an exception return from EL3.
  - If EL2 is implemented, it exists only in Non-secure state.
- If the implementation does not include EL3 it has one Security state, that is:
  - IMPLEMENTATION DEFINED, if the implementation does not include EL2.
  - Non-secure state if the implementation includes EL2.

### The AArch32 security model, and execution privilege

The Exception level hierarchy of four Exception levels, EL0, EL1, EL2, and EL3, applies to execution in both Execution states. This section describes the mapping between Exception levels, AArch32 modes, and Privilege levels.

The AArch32 modes Monitor, System, Supervisor, Abort, Undefined, IRQ, and FIQ all have the same privilege. In the AArch32 Privilege model this is PL1.

In Secure state:

- Monitor mode executes only at EL3, and is accessible only when EL3 is using AArch32.
- System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode all:
  - Execute at EL1 when EL3 is using AArch64.
  - Execute at EL3 when EL3 is using AArch32.

This means that there is a difference in the Secure state hierarchy that the PE is using, depending on which Execution state EL3 is using:

- If EL3 is using AArch64:
  - There is no support for Monitor mode.
  - If EL1 is using AArch32, System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL1.
- If EL3 is using AArch32:
  - Monitor mode is supported, and executes at Secure EL3
  - System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL3.
  - There is no support for a Secure EL1 Exception level.

See [Security behavior in Exception levels using AArch32 when EL3 is using AArch64](#) on page G1-3441 for more information about operation in a Secure EL1 mode when EL3 is using AArch64.

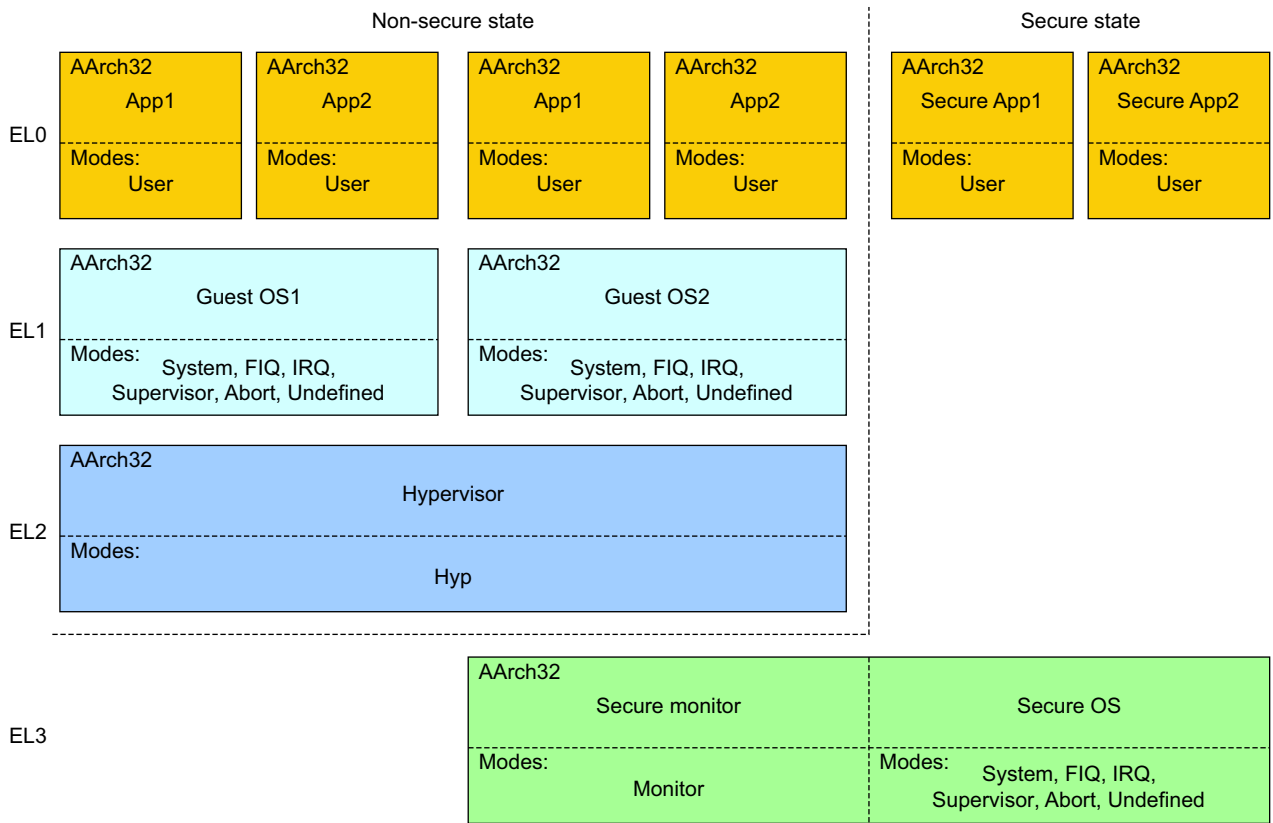

In Non-secure state, the PL1 modes System, Supervisor, Abort, Undefined, IRQ, and FIQ always execute at EL1.

User mode always executes at EL0 and has Privilege level PL0. Hyp mode always executes at EL2 and has Privilege level PL2. See [About the AArch32 PE modes](#) on page G1-3404.

———— **Note** ————

For more information about the Privilege level terminology, see [Execution privilege, Exception levels, and AArch32 Privilege levels](#) on page G3-3560.

Figure G1-1 shows the security model when EL3 is using AArch32, and shows the expected use of the different Exception levels, and which modes execute at which Exception levels.

**Figure G1-1 ARMv8-A Security model when EL3 is using AArch32**

———— **Note** ————

For an overview of the Security models when EL3 is using AArch64:

- See [Figure G1-2 on page G1-3415](#) for the case where EL2, EL1, and EL0 are all using AArch32. This figure shows the implementation of the PE modes.
- See [Figure D1-1 on page D1-1413](#) for an overview of the set of possible implementations.

Figure G1-1 on page G1-3408 shows that when EL3 is using AArch32, the Exception levels and modes available in each Security state are as follows:

#### Secure state

<b>EL0</b>	User mode.
<b>EL3</b>	Any mode that is available in Secure state, other than User mode.

#### Non-secure state

<b>EL0</b>	User mode.
<b>EL1</b>	Any mode that is available in Non-secure state, other than Hyp mode and User mode.
<b>EL2</b>	Hyp mode.

Execution at EL0 is described as *unprivileged execution*.

A mode associated with a particular Exception level,  $EL_n$ , is described as an  $EL_n$  mode.

---

#### Note

---

The Exception level defines the ability to access resources in the current Security state, and does not imply anything about the ability to access resources in the other Security state.

---

When EL3 is using AArch32, many AArch32 system registers accessible at PL1 are *banked* between the Secure and Non-secure states. This is compatible with the ARMv7-A Security Extensions.

When EL3 is using AArch64 and Secure EL1 is using AArch32, system registers accessible at PL1 are not banked between the Non-secure and Secure states. Software running at EL3 is expected to switch the content of the PL1 accessible system registers between the Secure and Non-secure context, in a similar manner to switching the contents of general purpose registers. For information on the relationship between AArch64 and AArch32 system registers in an interprocessing environment, see [Mapping of the System registers between the Execution states on page D1-1545](#).

For more information on the system registers, see [The conceptual coprocessor interface and system control on page G1-3492](#).

The *Secure Monitor Call* (SMC) instruction provides software with a system call to EL3. When executing at a privileged Exception level, SMC instructions generates exceptions. For more information, see [Secure Monitor Call \(SMC\) exception on page G1-3480](#) and [SMC \(previously SMI\) on page F7-3058](#).

---

#### Note

---

For more information about the Privilege level terminology, see [Execution privilege, Exception levels, and AArch32 Privilege levels on page G3-3560](#).

---

## Changing from Secure state to Non-secure state

Monitor mode is provided to support switching between Secure and Non-secure states. When executing in an Exception level that is using AArch32, except in Monitor mode and Hyp mode, the Security state is controlled:

- By the **SCR.NS** bit, when EL3 is using AArch32.
- By the **SCR\_EL3.NS** bit, when EL3 is using AArch64.

The mapping of AArch32 privileged modes to the exception hierarchy means that it is possible when EL3 is using AArch32 to change from EL3 to non-secure EL1 without an exception return. This can occur in one of the following ways:

- Using an MSR or CPS instruction to switch from Monitor mode to another privileged mode while **SCR.NS** is 1.
- Using an MCR instruction that writes **SCR.NS** to change from Secure to Non-secure state when in a privileged mode other than Monitor mode.

ARM strongly recommends that software executing at EL3 using AArch32 does not use either of these mechanisms to change from EL3 to non-secure EL1 without an exception return. The use of both of these mechanisms is deprecated.

## G1.8 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2. A PE is in *Hyp mode* when it is executing at EL2 in the AArch32 state. An exception return from Hyp mode to software running at EL1 or EL0 is performed using the ERET instruction.

EL2 provides a set of features that support virtualizing the Non-secure state of an ARMv8-A implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between *virtual machines*. A virtual machine is comprised of Non-secure EL1 and Non-secure EL0.
- A number of Guest operating systems, that each run in Non-secure EL1, on a virtual machine.
- For each Guest operating system, applications, that usually run in Non-secure EL0, on a virtual machine.

### ———— Note ————

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The ARMv8-A architecture supports both of these models.

The hypervisor assigns a *virtual machine identifier* (VMID) to each virtual machine.

EL2 is implemented only in Non-secure state, to support Guest OS management. EL2 provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.
- *Trap* various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2.
- Route interrupts to the appropriate one of:
  - The current Guest OS.
  - A Guest OS that is not currently running.
  - The hypervisor.

In Non-secure state:

- The implementation provides an independent *translation regime* for memory accesses from EL2.
- For the EL1&0 translation regime, address translation occurs in two stages:
  - Stage 1 maps the *Virtual Address* (VA) to an *Intermediate Physical Address* (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the *Physical Address* (PA).
  - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

For more information on the translation regimes, see [Chapter G3 The AArch32 Virtual Memory System Architecture](#).

### G1.8.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

- Hypervisor Call (HVC) exception.
- Traps to EL2. [AArch32 control of traps to the hypervisor on page G1-3503](#), describes these.
- All of the virtual interrupts:
  - Virtual External interrupt.
  - Virtual IRQ.
  - Virtual FIQ.

HVC exceptions are always taken to EL2. All virtual interrupts are always taken to EL1, and can only be taken from Non-secure EL1 or EL0.

Each of the virtual interrupts can be independently enabled using controls at EL2.

Each of the virtual interrupts has a corresponding physical interrupt. See [Virtual interrupts](#).

When a virtual interrupt is enabled, its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3. For more information, see [Asynchronous exception behavior for exceptions taken from AArch32 state](#) on page G1-3465.

An implementation that includes EL2 also:

- Provides controls that can be used to route some synchronous exceptions, taken from Non-secure state, to EL2. For more information see:
  - [Routing general exceptions to EL2](#) on page G1-3452.
  - [Routing Debug exceptions to Hyp mode](#) on page G1-3454.
- Provides mechanisms to trap PE operations to EL2. See [AArch32 control of traps to the hypervisor](#) on page G1-3503.

When an operation is trapped to EL2, the hypervisor typically either:

- Emulates the required operation. The application running in the Guest OS is unaware of the trap.
- Returns an error to the Guest OS.

## Virtual interrupts

The virtual interrupts have names that correspond to the physical interrupts, as shown in [Table G1-1](#).

**Table G1-1 The virtual interrupts**

Physical interrupt	Corresponding virtual interrupt
External abort	Virtual External Abort
IRQ	Virtual IRQ
FIQ	Virtual FIQ

Software executing at EL2 can use virtual interrupts to signal physical interrupts to Non-secure EL1 and Non-secure EL0. [Example G1-1](#) shows a usage model for virtual interrupts.

### Example G1-1 Virtual interrupt usage model

A usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.
2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:
  - If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
  - If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.

Non-secure EL1 and Non-secure EL0 modes cannot distinguish a virtual interrupt from the corresponding physical interrupt.

For more information see [Virtual exceptions when an implementation includes EL2](#) on page G1-3465.

## G1.9 AArch32 PE modes, general-purpose registers, and the PC

The following sections describe the AArch32 PE modes and the general-purpose registers and the PC:

- [AArch32 PE mode descriptions](#).
- [AArch32 general-purpose registers, and the PC](#) on page G1-3418.
- [Program Status Registers \(PSRs\)](#) on page G1-3422.
- [ELR\\_hyp](#) on page G1-3428.

———— **Note** —————

The PC is included in the scope of this section because, in AArch32 state, it is defined as being part of the same register file as the general-purpose registers. That is, the AArch32 register file R0-R15 comprises:

- The general-purpose registers R0-R14.
- The PC, that can be described as R15.

### G1.9.1 AArch32 PE mode descriptions

Table G1-2 shows the PE modes defined by the ARM architecture, for execution in AArch32 state. In this table:

- The *PE mode* column gives the name of each mode and the abbreviation used, for example, in the general-purpose register name suffixes used in [AArch32 general-purpose registers, and the PC](#) on page G1-3418.
- The *Encoding* column gives the corresponding CPSR.M field.
- The *Exception level* column gives the Exception level at which the mode is implemented, including dependencies on the current Security state and on whether EL3 is using AArch32, see [Exception levels](#) on page G1-3401.

**Table G1-2 AArch32 PE modes**

PE mode	Encoding	Security state	Exception level	Implemented
User	usr 10000	Both	EL0	Always
FIQ	fiq 10001	Non-secure Secure	EL1 EL1 or EL3 <sup>a</sup>	Always
IRQ	irq 10010	Non-secure Secure	EL1 EL1 or EL3 <sup>a</sup>	Always
Supervisor	svc 10011	Non-secure Secure	EL1 EL1 or EL3 <sup>a</sup>	Always
Monitor	mon 10110	Secure	EL3	If EL3 implemented and using AArch32
Abort	abt 10111	Non-secure Secure	EL1 EL1 or EL3 <sup>a</sup>	Always
Hyp	hyp 11010	Non-secure	EL2	If EL2 implemented and using AArch32
Undefined	und 11011	Non-secure Secure	EL1 EL1 or EL3 <sup>a</sup>	Always
System	sys 11111	Non-secure Secure	EL1 EL1 or EL3 <sup>a</sup>	Always

a. EL3 if EL3 is using AArch32. EL1 if EL3 is using AArch64 and EL1 is using AArch32.

Mode changes can be made under software control, or can be caused by an external or internal exception.

## Notes on the AArch32 PE modes

PE modes are defined only in AArch32. Because each mode is implemented as part of a particular Exception level that is using AArch32, the set of available modes depends on which Exception levels are implemented and using AArch32, as described in [Effect of the EL3 Execution state on the PE modes and Exception levels](#) on page G1-3415.

This section gives more information about each of the modes, when it is implemented.

**User mode** Software executing in User mode executes at EL0. Execution in User mode is sometimes described as unprivileged execution. Application programs normally execute in User mode, and any program executed in User mode:

- Makes only unprivileged accesses to system resources, meaning it cannot access protected system resources.
- Makes only unprivileged access to memory.
- Cannot change mode except by causing an exception, see [Handling exceptions that are taken to an Exception level using AArch32](#) on page G1-3431.

**System mode** System mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels](#) on page G1-3415.

System mode has the same registers available as User mode, and is not entered by any exception.

### Supervisor mode

Supervisor mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels](#) on page G1-3415.

Supervisor mode is the default mode to which a Supervisor Call exception is taken. Executing a SVC (Supervisor Call) instruction generates a Supervisor Call exception.

In an implementation where the highest implemented Exception level is using AArch32, if that Exception level is EL3 or EL1, a PE enters Supervisor mode on Reset.

**Abort mode** Abort mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels](#) on page G1-3415.

Abort mode is the default mode to which a Data Abort exception or Prefetch Abort exception is taken.

### Undefined mode

Undefined mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels](#) on page G1-3415.

Undefined mode is the default mode to which an instruction-related exception, including any attempt to execute an UNDEFINED instruction, is taken.

**FIQ mode** FIQ mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels](#) on page G1-3415.

FIQ mode is the default mode to which an FIQ interrupt is taken.

**IRQ mode** IRQ mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels](#) on page G1-3415.

IRQ mode is the default mode to which an IRQ interrupt is taken.

**Hyp mode** Hyp mode is the Non-secure EL2 mode.

Hyp mode is entered on taking an exception from Non-secure state that must be taken to EL2.

In an implementation where the highest implemented Exception level is EL2 and EL2 uses AArch32 on reset, a PE enters Hyp mode on Reset.

The Hypervisor Call exception and Hyp Trap exception are implemented as part of EL2 and are always taken to Hyp mode.

---

**Note**

This means that Hypervisor Call and Hyp Trap exceptions cannot be taken from Secure state.

---

When the value of the Hypervisor Call enable bit, `SCR.HCE`, is 1, executing a HVC (Hypervisor Call) instruction in a Non-secure EL1 mode generates a Hypervisor Call exception.

For more information, see [Hyp mode on page G1-3416](#).

### Monitor mode

Monitor mode is the Secure EL3 mode. This means it is always in the Secure state, regardless of the value of the `SCR.NS` bit.

Monitor mode is the mode to which a Secure Monitor Call exception is taken. In a Non-secure EL1 mode, or a Secure EL3 mode, executing an SMC (Secure Monitor Call) instruction generates a Secure Monitor Call exception.

When EL3 is using AArch32, some exceptions that are taken to a different mode by default can be configured to be taken to EL3, see [PE mode for taking exceptions on page G1-3439](#).

When EL3 is using AArch32, software executing in Monitor mode:

- Has access to both the Secure and Non-secure copies of System registers.
- Can perform an exception return to Secure state, or to Non-secure state.

This means that, when EL3 is using AArch32, Monitor mode provides the only recommended method of changing between the Secure and Non-secure Security states.

### Secure and Non-secure modes

In an implementation that includes EL3, the names of most implemented modes can be qualified as Secure or Non-secure, to indicate whether the PE is also in Secure state or Non-secure state. For example:

- If a PE is in Supervisor mode and Secure state, it is in *Secure Supervisor mode*.
- If a PE is in User mode and Non-secure state, it is in *Non-secure User mode*.

---

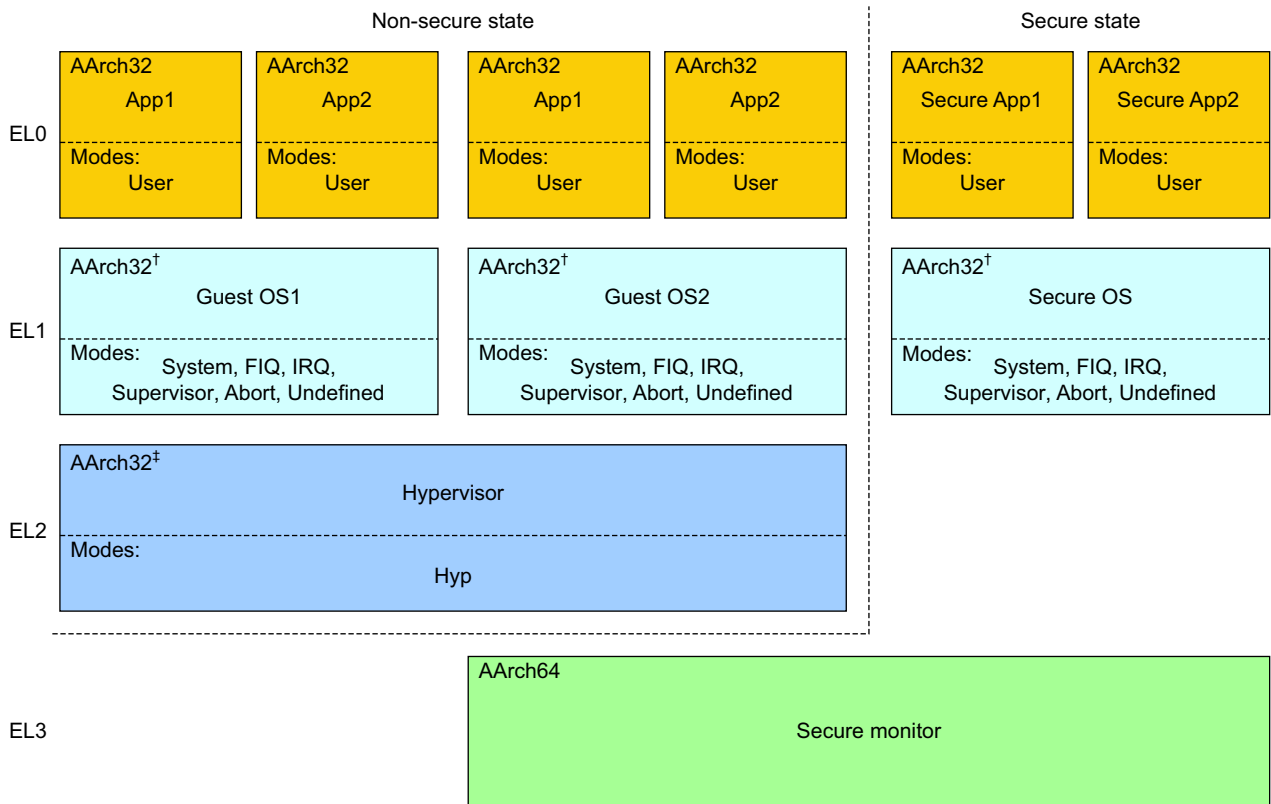

**Note**

As indicated in the appropriate Mode descriptions:

- Monitor mode is a Secure mode, meaning it is always in the Secure state.
  - Hyp mode is a Non-secure mode, meaning it is accessible only in Non-secure state.
-

**Effect of the EL3 Execution state on the PE modes and Exception levels**

Figure G1-1 on page G1-3408 shows the PE modes, Exception levels, and Security states, for an implementation that includes all of the Exception levels, when EL3 is using AArch32. Figure G1-2 shows how the implemented modes change when EL3 is using AArch64.

† When EL1 is using AArch64, System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are not implemented

‡ When EL2 is using AArch64, Hyp mode is not implemented

**Figure G1-2 ARMv8 Exception levels, and PE modes, when EL3 is using AArch64**

Comparing Figure G1-1 on page G1-3408 and Figure G1-2 shows how, in Secure state only, the implementation of System, FIQ, IRQ, Supervisor, Abort, and Undefined mode depends on the Execution state that EL3 is using. That is, these modes are implemented as follows:

**Non-secure state**

If Non-secure EL1 is using AArch32 then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Non-secure state.

**Secure state** The implementation of these modes depends on the Execution state that EL3 is using, as follows:

**EL3 using AArch64** If Secure EL1 is using AArch32 then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Secure state.

**EL3 using AArch32** In Secure state, System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL3, see Figure G1-1 on page G1-3408.

## Hyp mode

Hyp mode is the Non-secure EL2 mode. When EL2 is using AArch32, it provides the usual method of controlling the virtualization of Non-secure execution at EL1 and EL0.

---

### Note

The alternative method of controlling this functionality is by accessing the EL2 controls from EL3 with the [SCR\\_EL3.NS](#) or [SCR.NS](#) bit set to 1.

---

This section summarizes how Hyp mode differs from the other modes, and references where this part of the manual describes the features of Hyp mode in more detail:

- Software executing in Hyp mode executes at EL2, see [Figure G1-1 on page G1-3408](#).
- Hyp mode is accessible only in Non-secure state. When the PE is in Secure state, setting [CPSR.M](#) to 0b11010, the encoding for Hyp mode, has no meaning. Therefore, in Secure state, the effect of attempting to set [CPSR.M](#) to 0b11010 is UNPREDICTABLE. For more information see [The Current Program Status Register \(CPSR\) on page G1-3422](#).
- In Non-debug state, the only mechanisms for changing to Hyp mode are:
  - An exception taken from a Non-secure EL1 or EL0 mode.
  - When EL3 is using AArch32, an exception return from Secure Monitor mode.
  - When EL3 is using AArch64, an exception return from EL3.
- In Hyp mode, the only exception return is execution of an ERET instruction, see [ERET on page F7-3038](#).
- In Hyp mode, the [CPACR](#) has no effect on the execution of coprocessor, floating-point, or Advanced SIMD instructions. The [HCPTR](#) controls execution of these instructions in Hyp mode.
- If software running in Hyp mode executes an SVC instruction, the Supervisor Call exception generated by the instruction is taken to Hyp mode, see [SVC \(previously SWI\) on page F7-2926](#).
- The effect of an exception return with the restored [CPSR](#) specifying Hyp mode is UNPREDICTABLE if any of the following applies:
  - EL3 is using AArch64 and the value of [SCR\\_EL3.NS](#) is 0.
  - EL3 is using AArch32 and the value of [SCR.NS](#) is 0.
  - The return is from a Non-secure EL1 mode.
- The instructions described in the following sections are UNDEFINED if executed in Hyp mode:
  - [SRS \(T32\) on page F7-3060](#).
  - [SRS \(A32\) on page F7-3062](#).
  - [RFE on page F7-3056](#).
  - [LDM \(exception return\) on page F7-3042](#).
  - [LDM \(User registers\) on page F7-3044](#).
  - [STM \(User registers\) on page F7-3064](#).
  - [SUBS PC, LR and related instructions \(A32\) on page F7-3068](#).
  - [SUBS PC, LR and related instructions \(T32\) on page F7-3066](#), when executed with a nonzero constant.

---

### Note

In T32 state, ERET is encoded as SUBS PC, LR, #0, and therefore this is a valid instruction.

---

- The unprivileged Load unprivileged and Store unprivileged instructions LDRT, LDRSHT, LDRHT, LDRBT, STRT, STRHT, and STRBT, are UNPREDICTABLE if executed in Hyp mode.

In an implementation that includes EL3, from reset, the HVC instruction is UNDEFINED in Non-secure EL1 modes, meaning entry to Hyp mode is disabled by default. To permit entry to Hyp mode using the Hypervisor Call exception, Secure software must enable use of the HVC instruction:

- By setting the `SCR_EL3.HCE` bit to 1, if EL3 is using AArch64.
- By setting the `SCR.HCE` bit to 1, if EL3 is using AArch32.

When the HVC instruction is UNDEFINED in Non-secure EL1 modes because of the value of the `SCR_EL3.HCE` or `SCR.HCE` bit, HVC is UNPREDICTABLE in Hyp mode.

## Pseudocode details of mode operations

The `BadMode()` function tests whether a 5-bit mode number corresponds to one of the permitted modes:

```
// BadMode()
// =====

boolean BadMode(bits(5) mode)
    case mode of
        when M32_User      result = FALSE;
        when M32_FIQ      result = FALSE;
        when M32_IRQ      result = FALSE;
        when M32_Svc      result = FALSE;
        when M32_Monitor  result = !HaveEL(EL3);
        when M32_Abort    result = FALSE;
        when M32_Hyp      result = !HaveEL(EL2);
        when M32_Undef    result = FALSE;
        when M32_System   result = FALSE;
        otherwise         result = TRUE;
    return result;
```

The following pseudocode functions provide information about the current mode:

```
// CurrentModeIsNotUser()
// =====

boolean CurrentModeIsNotUser()
    if BadMode(CPSR.M) then UNPREDICTABLE;
    if CPSR.M == M32_User then return FALSE;
    return TRUE; // Other modes

// CurrentModeIsUserOrSystem()
// =====

boolean CurrentModeIsUserOrSystem()
    if BadMode(CPSR.M) then UNPREDICTABLE;
    if CPSR.M == M32_User then return TRUE;
    if CPSR.M == M32_System then return TRUE;
    return FALSE; // Other modes

// CurrentModeIsHyp()
// =====

boolean CurrentModeIsHyp()
    if BadMode(CPSR.M) then UNPREDICTABLE;
    if CPSR.M == M32_Hyp then return TRUE;
    return FALSE; // Other modes
```

## G1.9.2 AArch32 general-purpose registers, and the PC

The *general-purpose registers, and the PC, in AArch32 state* on page E1-2294 describes the application level view of the general-purpose registers, and the PC. This view provides:

- The general-purpose registers R0-R14, of which:
  - The preferred name for R13 is SP (*stack pointer*).
  - The preferred name for R14 is LR (*link register*).
- The PC (*program counter*), that can be described as R15.

These registers are selected from a larger set of registers, that includes *Banked* copies of some registers, with the current register selected by the execution mode. The implementation and banking of the general-purpose registers depends on whether or not the implementation includes EL2 and EL3, and whether those exception levels are using AArch32. Figure G1-3 shows the full set of Banked general-purpose registers, the Program Status Registers CPSR and SPSR, and the ELR\_hyp Special register.

———— **Note** —————

The architecture uses system level register names, such as R0\_usr, R8\_usr, and R8\_fiq, when it must identify a specific register. The application level names refer to the registers for the current mode, and usually are sufficient to identify a register.

Application level view	System level view								
	User	System	Hyp <sup>†</sup>	Supervisor	Abort	Undefined	Monitor <sup>‡</sup>	IRQ	FIQ
R0	R0_usr								
R1	R1_usr								
R2	R2_usr								
R3	R3_usr								
R4	R4_usr								
R5	R5_usr								
R6	R6_usr								
R7	R7_usr								
R8	R8_usr								R8_fiq
R9	R9_usr								R9_fiq
R10	R10_usr								R10_fiq
R11	R11_usr								R11_fiq
R12	R12_usr								R12_fiq
SP	SP_usr		SP_hyp	SP_svc	SP_abt	SP_und	SP_mon	SP_irq	SP_fiq
LR	LR_usr			LR_svc	LR_abt	LR_und	LR_mon	LR_irq	LR_fiq
PC	PC

‡ Part of EL3. Exists only in Secure state, and only when EL3 is using AArch32.

† Part of EL2. Exists only in Non-secure state, and only when EL2 is using AArch32.

Cells with no entry indicate that the User mode register is used.

**Figure G1-3 AArch32 general-purpose registers, the PC, PSRs, and ELR\_hyp, showing register banking**

As described in *PE mode for taking exceptions* on page G1-3439, on taking an exception the PE changes mode, unless it is already in the mode to which it must take the exception. Each mode that the PE might enter in this way has:

- A Banked copy of the stack pointer, for example SP\_irq and SP\_hyp.
- A register that holds a preferred return address for the exception. This is:
  - For the EL2 mode, Hyp mode, the special register ELR\_hyp.
  - For the other privileged modes to which exceptions can be taken, a Banked copy of the link register, for example LR\_und and LR\_mon.
- A saved copy of the CPSR, made on exception entry, for example SPSR\_irq and SPSR\_hyp.

In addition FIQ mode has Banked copies of the general-purpose registers R8 to R12.

User mode and System mode share the same general-purpose registers.

User mode, System mode, and Hyp mode share the same LR.

For more information about the application level view of the SP, LR, and PC, and the alternative descriptions of them as R13, R14 and R15, see *The general-purpose registers, and the PC, in AArch32 state* on page E1-2294.

## Pseudocode details of general-purpose register and PC operations

The following pseudocode gives access to the general-purpose registers and the PC,

\_R is the array of general-purpose registers. This array is common to AArch32 and AArch64 operation and therefore contains 31 64-bit registers. \_PC is the program counter, and its definition is common to AArch32 and AArch64 operation and therefore its size is 64-bit.

```
array bits(64) _R[0..30];
```

```
bits(64) _PC;
```

LookUpRIndex() looks up the \_R entry for the specified register number and PE mode, using RBankSelect() to evaluates the result.

```
// LookUpRIndex()
// =====
```

```
integer LookUpRIndex(integer n, bits(5) mode)
  assert n >= 0 && n <= 14;
```

```
  case n of // Select index by mode:   usr fiq irq svc abt und hyp
    when 8   result = RBankSelect(mode, 8, 24, 8, 8, 8, 8, 8);
    when 9   result = RBankSelect(mode, 9, 25, 9, 9, 9, 9, 9);
    when 10  result = RBankSelect(mode, 10, 26, 10, 10, 10, 10, 10);
    when 11  result = RBankSelect(mode, 11, 27, 11, 11, 11, 11, 11);
    when 12  result = RBankSelect(mode, 12, 28, 12, 12, 12, 12, 12);
    when 13  result = RBankSelect(mode, 13, 29, 17, 19, 21, 23, 15);
    when 14  result = RBankSelect(mode, 14, 30, 16, 18, 20, 22, 14);
    otherwise result = n;
```

```
  return result;
```

```
// RBankSelect()
// =====
```

```
integer RBankSelect(bits(5) mode, integer usr, integer fiq, integer irq,
  integer svc, integer abt, integer und, integer hyp)
```

```
  case mode of
    when M32_User   result = usr; // User mode
    when M32_FIQ    result = fiq; // FIQ mode
    when M32_IRQ    result = irq; // IRQ mode
    when M32_Svc    result = svc; // Supervisor mode
    when M32_Abort  result = abt; // Abort mode
    when M32_Hyp    result = hyp; // Hyp mode
```

```

    when M32_Undef    result = und; // Undefined mode
    when M32_System  result = usr; // System mode uses User mode registers
    otherwise        Unreachable(); // Monitor mode

return result;

```

R[] accesses the specified general-purpose register in the current PE mode, using Rmode[] to access the register, accessing \_R if necessary. SP accesses the stack pointer, LR accesses the link register, and PC accesses the program counter. Each function has a non-assignment form for register reads and an assignment form for register writes, other than PC, which has only a non-assignment form.

```

// R[] - assignment form
// =====

R[integer n] = bits(32) value
    Rmode[n, PSTATE.M] = value;
    return;

// R[] - non-assignment form
// =====

bits(32) R[integer n]
    if n == 15 then
        offset = (if CurrentInstrSet() == InstrSet_A32 then 8 else 4);
        return _PC<31:0> + offset;
    else
        return Rmode[n, PSTATE.M];

// Rmode[] - non-assignment form
// =====

bits(32) Rmode[integer n, bits(5) mode]
    assert n >= 0 && n <= 14;

    // Check for attempted use of Monitor mode in Non-secure state.
    if !IsSecure() then assert mode != M32_Monitor;
    assert !BadMode(mode);

    if mode == M32_Monitor && n == 13 then
        return SP_mon;
    elsif mode == M32_Monitor && n == 14 then
        return LR_mon;
    else
        return _R[LookUpRIndex(n, mode)]<31:0>;

// Rmode[] - assignment form
// =====

Rmode[integer n, bits(5) mode] = bits(32) value
    assert n >= 0 && n <= 14;

    // Check for attempted use of Monitor mode in Non-secure state.
    if !IsSecure() then assert mode != M32_Monitor;
    assert !BadMode(mode);

    if mode == M32_Monitor && n == 13 then
        SP_mon = value;
    elsif mode == M32_Monitor && n == 14 then
        LR_mon = value;
    else
        // It is CONSTRAINED UNPREDICTABLE whether the upper 32 bits of the X
        // register are unchanged or set to zero. This is also tested for on
        // exception entry, as this applies to all AArch32 registers.
        if ConstrainUnpredictableBool() then
            _R[LookUpRIndex(n, mode)] = ZeroExtend(value);
        else
            _R[LookUpRIndex(n, mode)]<31:0> = value;

```

```

    return;

// SP - assignment form
// =====

SP = bits(32) value
  R[13] = value;
  return;

// SP - non-assignment form
// =====

bits(32) SP
  return R[13];

// LR - assignment form
// =====

LR = bits(32) value
  R[14] = value;
  return;

// LR - non-assignment form
// =====

bits(32) LR
  return R[14];

// PC - non-assignment form
// =====

bits(32) PC
  return R[15];          // This includes the offset from AArch32 state

```

BranchTo() performs a branch to the specified address.

```

// BranchTo()
// =====

// Set program counter to a new address, with a branch reason hint
// for possible use by hardware fetching the next instruction.

BranchTo(bits(N) target, BranchType branch_type)
  HintBranch(branch_type);
  if N == 32 then
    assert UsingAArch32();
    _PC = ZeroExtend(target);
  else
    assert N == 64 && !UsingAArch32();
    // Remove the tag bits from a tagged target
    case PSTATE.EL of
      when EL0, EL1
        if target<55> == '1' && TCR_EL1.TBI1 == '1' then
          target<63:56> = '11111111';
        if target<55> == '0' && TCR_EL1.TBI0 == '1' then
          target<63:56> = '00000000';
      when EL2
        if TCR_EL2.TBI == '1' then
          target<63:56> = '00000000';
      when EL3
        if TCR_EL3.TBI == '1' then
          target<63:56> = '00000000';
    _PC = target<63:0>;
  return;

```

### G1.9.3 Program Status Registers (PSRs)

In AArch32 state, the Application level programmers' model provides the Application Program Status Register, see [The Application Program Status Register \(APSR\) on page E1-2297](#). This is an application level alias for the *Current Program Status Register (CPSR)*. The system level view of the **CPSR** extends the register, adding system level information.

Every mode that an exception can be taken to has its own saved copy of the **CPSR**, the *Saved Program Status Register (SPSR)*, as shown in [Figure G1-3 on page G1-3418](#). For example, the **SPSR** for Monitor mode is called **SPSR\_mon**.

———— **Note** ————

The information held in the **APSR** and **CPSR** is part of the ARMv8 **PSTATE** information, described in [Process state, PSTATE on page D1-1421](#). Unlike the AArch32 **CPSR**, AArch64 state supports instructions that operate on elements of **PSTATE**, but its programmers' model does not include a register that gives access to all of **PSTATE**.

#### The Current Program Status Register (CPSR)

In AArch32 state, the *Current Program Status Register (CPSR)* holds PE status and control information. This means it holds:

- The **APSR**, see [The Application Program Status Register \(APSR\) on page E1-2297](#).
- The current instruction set state, see [Instruction set state register, ISETSTATE on page E1-2298](#).
- The execution state bits for the T32 If-Then instruction, see [IT block state register, ITSTATE on page E1-2300](#).
- The current endianness, see [Endianness mapping register, ENDIANSTATE on page E1-2302](#).
- The current PE mode.
- Interrupt and asynchronous abort disable bits.

The non-**APSR** bits of the **CPSR** have defined reset values. These are shown in the `TakeReset()` pseudocode function, see [Reset on page G1-3475](#).

Writes to the **CPSR** have side-effects on various aspects of PE operation. All of these side-effects, except for those on memory accesses associated with fetching instructions, are synchronous to the **CPSR** write. This means they are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

The privilege level and address space of memory accesses associated with fetching instructions depend on the current Exception level and Security state. Writes to **CPSR.M** can change one or both of the Exception level and Security state. The effect, on memory accesses associated with fetching instructions, of a change of Exception level or Security state is:

- Synchronous to the change of Exception level or Security state, if that change is caused by an exception entry or exception return.
- Guaranteed not to be visible to any memory access caused by fetching an earlier instruction in the execution stream.
- Guaranteed to be visible to any memory access caused by fetching any instruction after the next context synchronization operation in the execution stream.

———— **Note** ————

See [Context synchronization operation](#) for the definition of this term.

- Might or might not affect memory accesses caused by fetching instructions between the mode change instruction and the point where the mode change is guaranteed to be visible.

See [Exception return to an Exception level using AArch32 on page G1-3454](#) for the definition of exception return instructions.

## The Saved Program Status Registers (SPSRs)

The purpose of an **SPSR** is to record the pre-exception value of the **CPSR**. On taking an exception, the **CPSR** is copied to the **SPSR** of the mode to which the exception is taken. Saving this value means the exception handler can:

- On exception return, restore the **CPSR** to the value it had immediately before the exception was taken.
- Examine the value that the **CPSR** had when the exception was taken, for example to determine the instruction set state and privilege level in which the instruction that caused an Undefined Instruction exception was executed.

Figure G1-3 on page G1-3418 shows the banking of the SPSRs.

The SPSRs are UNKNOWN on reset. Any operation in a Non-secure EL1 or EL0 mode makes **SPSR\_hyp** UNKNOWN.

## Format of the CPSR and SPSRs

The CPSR and SPSR bit assignments are:

### Condition flags, bits[31:28]

Set on the result of instruction execution. The flags are:

**N, bit[31]** Negative condition flag.

**Z, bit[30]** Zero condition flag.

**C, bit[29]** Carry condition flag.

**V, bit[28]** Overflow condition flag.

The condition flags can be read or written in any mode, and are described in *IT block state register, ITSTATE* on page E1-2300.

**Q, bit[27]** Cumulative saturation bit. This bit can be read or written in any mode, and is described in *IT block state register, ITSTATE* on page E1-2300.

### IT[7:0], bits[15:10, 26:25]

If-Then execution state bits for the T32 IT (If-Then) instruction. *IT block state register, ITSTATE* on page E1-2300 describes the encoding of these bits. **CPSR.IT[7:0]** are the **IT[7:0]** bits described there. For more information, see *IT* on page F7-2610.

For details of how these bits can be accessed see *Accessing the execution state bits* on page G1-3425.

**J, bit[24]** J bit, see the description of the T bit, bit[5].

**Bits[23:22]** Reserved. RAZ/SBZP.

**SS, bit[21]** Software step bit, used for tracking the progress of software step debug. **SPSR.SS** is used by a debugger to initiate a Software Step debug event. It also indicates which software step state machine state the PE was in. See *Software Step exceptions* on page D2-1634.

This bit is **RES0** in the **CPSR**.

**IL, bit[20]** Illegal state or Mode bit. Holds the value of **PSTATE.IL**. The **IL** bit is set to 1 in AArch32 state to indicate that on exception return or as a result of an explicit change of the **CPSR.M** field, an illegal state or mode was indicated. In an **SPSR**, the **IL** bit shows the value of **PSTATE.IL** immediately before the exception was taken.

This bit is **RES0** in the **CPSR**.

————— **Note** —————

Conceptually, CPSR.IL holds the value of PSTATE.IL. However, when PSTATE.IL is set to 1, execution of any instruction generates an exception, and therefore a CPSR.IL value of 1 could never be observed, and the observed behavior of this CPSR bit is RES0.

For more information see [Illegal exception returns to AArch32 state](#) on page G1-3456.

**GE[3:0], bits[19:16]**

Greater than or Equal flags, for the parallel addition and subtraction (SIMD) instructions described in [Parallel addition and subtraction instructions](#) on page F1-2389.

The GE[3:0] field can be read or written in any mode, and is described in [The Application Program Status Register \(APSR\)](#) on page E1-2297.

**E, bit[9]**

Endianness execution state bit. Controls the load and store endianness for data accesses:

**0** Little-endian operation.

**1** Big-endian operation.

Instruction fetches ignore this bit.

[Endianness mapping register, ENDIANSTATE](#) on page E1-2302 describes the encoding of this bit. CPSR.E is the ENDIANSTATE bit described there.

For details of how this bit can be accessed see [Accessing the execution state bits](#) on page G1-3425.

When the reset value of the SCTL.R.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

**Mask bits, bits[8:6]**

These bits are:

**A, bit[8]** Asynchronous abort mask bit.

**I, bit[7]** IRQ mask bit.

**F, bit[6]** FIQ mask bit.

The possible values of each bit are:

**0** Exception not masked.

**1** Exception masked.

The A bit has no effect on any Data Abort exception generated by a Watchpoint debug event, even if that exception is asynchronous. For more information see [Breakpoint and Watchpoint debug events](#) on page H2-4330.

In an implementation that does not include EL3, setting a mask bit masks the corresponding exception, meaning it cannot be taken. However, the implementation of EL3 and EL2 significantly alters the behavior and effect of these bits, see [Effects of EL3 and EL2 on the CPSR.{A, F} bits](#) on page G1-3425 and [Asynchronous exception masking controls](#) on page G1-3468.

The mask bits can be written only at EL1 or higher. Their values can be read in any mode, but ARM deprecates any use of their values, or attempt to change them, by software executing at EL0.

**T, bit[5]**

T32 execution state bit. This bit and the J execution state bit, bit[24], determine the instruction set state of the PE, A32 or T32. [Instruction set state register, ISETSTATE](#) on page E1-2298 describes the encoding of these bits. CPSR.J and CPSR.T are the same bits as ISETSTATE.J and ISETSTATE.T respectively. For more information, see [Instruction set states](#) on page G1-3429.

For details of how these bits can be accessed see [Accessing the execution state bits](#) on page G1-3425.

**M[4:0], bits[4:0]**

Mode field. This field determines the current mode of the PE. The permitted values of this field are listed in [Table G1-2](#) on page G1-3412. All other values of M[4:0] are reserved. [Illegal changes to the CPSR.M field](#) on page G1-3458 describes the effect of setting M[4:0] to a reserved value.

ARMv8 redefines M[4] as follows:

**M[4], Execution state** This bit indicates the Execution state of the PE, as follows:

<b>0</b>	AArch64 state.
<b>1</b>	AArch32 state.

———— **Note** ————

This is consistent with the use of the M[4:0] field in previous versions of the architecture. All of the PE modes have M[4:0] values in which the value of the most significant bit is 1.

For more information about the PE modes see [AArch32 PE mode descriptions on page G1-3412](#). [Figure G1-3 on page G1-3418](#) shows the registers that can be accessed in each mode.

This field can be written only at EL1 or higher. Its value can be read in any mode, but ARM deprecates software executing at ELO making any use of its value, or attempting to change it.

### Accessing the execution state bits

The execution state bits are the IT[7:0], J, E, and T bits. If the current mode has an [SPSR](#), software can read or write these bits in the [SPSR](#).

In the [CPSR](#), unless the PE is in Debug state:

- The execution state bits, other than the E bit, are RAZ when read by an MRS instruction.
- Writes to the execution state bits, other than the E bit, by an MSR instruction are ignored in all modes.

Instructions other than MRS and MSR that access the execution state bits can read and write them in any mode.

Unlike the other execution state bits in the [CPSR](#), [CPSR.E](#) can be read by an MRS instruction and written by an MSR instruction. However, ARM deprecates:

- Using the [CPSR.E](#) value read by an MRS instruction.
- Using an MSR instruction to change the value of [CPSR.E](#).

———— **Note** ————

- Software can use the SETEND instruction to change the current endianness.
- To determine the current endianness, software can use an LDR instruction to load a word of memory with a known value that differs if the endianness is reversed. For example, using an LDR (literal) instruction to load a word whose four bytes are 0x01, 0x00, 0x00, and 0x00 in ascending order of memory address loads the destination register with:
  - 0x00000001 if the current endianness is little-endian.
  - 0x01000000 if the current endianness is big-endian.

For more information about the behavior of these bits in Debug state see [Status register access instructions on page F1-2391](#).

### Effects of EL3 and EL2 on the CPSR.{A, F} bits

In an implementation that includes EL3, the [SCR](#).{AW, FW} bits modify the effect of the [CPSR](#).{A, F} bits on exceptions taken from Non-secure state.

In an implementation that includes EL2, the [HCR](#).{AMO, IMO, FMO} bits modify the effect of the [CPSR](#).{A, I, F} bits on exceptions taken from Non-secure state.

For more information see [Asynchronous exception masking controls on page G1-3468](#).

Privileged software can change the `CPSR`.{A, F} and `SPSR`.{A, F} bits. In an implementation that includes EL3, this is true regardless of the value of the corresponding `SCR`.{AW, FW} bits. However, when the `SPSR` is copied to the `CPSR`, a `CPSR`.{A, F} bit is not updated if the value of the corresponding `SCR`.{AW, FW} bit is 0.

———— **Note** ————

In ARMv7 implementations before the introduction of the Virtualization Extensions, the `SCR`.{AW, FW} bits control whether the `CPSR`.{A, F} bits are writable in Non-secure state. In ARMv8, the `SCR`.{AW, FW} bits never have this effect.

## Pseudocode details of PSR operations

The following pseudocode gives access to the PSRs. The `SPSR[]` function accesses the current `SPSR`, and is common to AArch32 and AArch64 operation. The `CPSR[]` function accesses the `CPSR`. Each of these functions has non-assignment form for reads and an assignment form for writes.

bits(32) `CPSR`, `SPSR_fiq`, `SPSR_irq`, `SPSR_svc`, `SPSR_mon`, `SPSR_abt`, `SPSR_und`, `SPSR_hyp`;

```
// SPSR[] - non-assignment form
// =====

bits(32) SPSR[]
  bits(32) result;
  if UsingAArch32() then
    case CPSR.M of
      when M32_FIQ      result = SPSR_fiq;
      when M32_IRQ      result = SPSR_irq;
      when M32_Svc      result = SPSR_svc;
      when M32_Monitor  result = SPSR_mon;
      when M32_Abort    result = SPSR_abt;
      when M32_Hyp      result = SPSR_hyp;
      when M32_Undef    result = SPSR_und;
      otherwise         Unreachable();
    else
      case PSTATE.EL of
        when EL1        result = SPSR_EL1;
        when EL2        result = SPSR_EL2;
        when EL3        result = SPSR_EL3;
        otherwise       Unreachable();

  return result;

// SPSR[] - assignment form
// =====

SPSR[] = bits(32) value
  if UsingAArch32() then
    case CPSR.M of
      when M32_FIQ      SPSR_fiq = value;
      when M32_IRQ      SPSR_irq = value;
      when M32_Svc      SPSR_svc = value;
      when M32_Monitor  SPSR_mon = value;
      when M32_Abort    SPSR_abt = value;
      when M32_Hyp      SPSR_hyp = value;
      when M32_Undef    SPSR_und = value;
      otherwise         Unreachable();
    else
      case PSTATE.EL of
        when EL1        SPSR_EL1 = value;
        when EL2        SPSR_EL2 = value;
        when EL3        SPSR_EL3 = value;
        otherwise       Unreachable();

  return;
```

```

// CPSR - non-assignment form
// =====

    if privileged then
      new_cpsr<4:0> = value<4:0>; // mode bits

  // Attempts to change to an illegal mode, or return to Hyp mode with CPSR.<J,T> = '11'
  // will invoke the Illegal Execution State mechanism
  CPSR = new_cpsr; // Assign new CPSR value

  return;

// SPSRWriteByInstr()
// =====

SPSRWriteByInstr(bits(32) value, bits(4) bytemask)

  if CurrentModeIsUserOrSystem() then UNPREDICTABLE;

  if bytemask<3> == '1' then
    SPSR[]<31:24> = value<31:24>; // N,Z,C,V,Q flags, IT<1:0>,J execution state bits

  if bytemask<2> == '1' then
    // bits <23:20> are reserved SBZP bits
    SPSR[]<19:16> = value<19:16>; // GE<3:0> flags

  if bytemask<1> == '1' then

```

```
SPSR[]<15:8> = value<15:8>; // IT<7:2> execution state bits, E bit, A interrupt mask

if bytemask<0> == '1' then
    SPSR[]<7:5> = value<7:5>; // I,F interrupt masks, T execution state bit
    if BadMode(value<4:0>) then // Mode bits
        UNPREDICTABLE;
    else
        SPSR[]<4:0> = value<4:0>;

return;
```

#### G1.9.4 ELR\_hyp

Hyp mode does not provide its own Banked copy of LR. Instead, on taking an exception to Hyp mode, the preferred return address is stored in ELR\_hyp, a 32-bit Special register implemented for this purpose.

ELR\_hyp can be accessed explicitly only by executing:

- An MRS or MSR instruction that targets ELR\_hyp, see:
  - [MRS \(Banked register\) on page F7-2721](#).
  - [MSR \(Banked register\) on page F7-2726](#).

The ERET instruction uses the value in ELR\_hyp as the return address for the exception. For more information, see [ERET on page F7-2607](#).

Software execution in any Non-secure EL1 or EL0 mode makes ELR\_hyp UNKNOWN.

## G1.10 Instruction set states

The instruction set states are described in [Chapter E2 The AArch32 Application Level Memory Model](#) and application level operations on them are described there. This section supplies more information about how they interact with system level functionality, in the sections:

- [Exceptions and instruction set state](#).
- [Unimplemented instruction sets](#).

### G1.10.1 Exceptions and instruction set state

If an exception is taken to a EL1 mode, the [SCTLR.TE](#) bit for the Security state the exception is taken to determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

If the exception is taken to Hyp mode, the [HSCTLR.TE](#) bit determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

On coming out of reset, if the highest implemented Exception level is using AArch32:

- If the highest implemented Exception level is EL2, the PE starts execution in Hyp mode, in the instruction set state determined by the reset value of [HSCTLR.TE](#).
- Otherwise, the PE starts execution in Supervisor mode, in the instruction set state determined by the reset value of [SCTLR.TE](#). If the implementation includes EL3, this execution is in Secure Supervisor mode.

For more information about exception entry see [Overview of exception entry on page G1-3436](#).

### G1.10.2 Unimplemented instruction sets

The [CPSR.J](#) and [CPSR.T](#) bits define the current instruction set state, see [Instruction set state register, ISETSTATE on page E1-2298](#).

In the ARMv8 architecture:

- There is no support for the hardware acceleration of Java bytecodes, and the Jazelle Instruction set state is obsolete. Every AArch32 implementation must support the Trivial Jazelle implementation described in [Trivial implementation of the Jazelle extension](#).
- The T32EE state is OPTIONAL and deprecated in the ARMv8 architecture. ARM strongly recommends that T23EE state is not supported in any ARMv8 implementation.

Some system instructions permit setting [CPSR.{J, T}](#) to values that select an unimplemented instruction set state, for example setting [CPSR.J](#) to 1 and [CPSR.T](#) to 0 on an PE that does not implement the Jazelle state. If such values are written to [CPSR.{J, T}](#), the implementation behaves in one of these ways:

- Sets [CPSR.{J, T}](#) to the requested values and causes the next instruction to generate an Undefined Instruction exception, as described in [Exception return to an unimplemented instruction set state on page G1-3458](#).
- Does not set [CPSR.{J, T}](#) to the requested values. The PE might change the value of one or both of the bits in such a way that the new values correspond to an implemented instruction set state. If this is done then the instruction set state changes to this new state. The detailed behavior of the attempt to change to an unimplemented state is IMPLEMENTATION DEFINED.

#### Trivial implementation of the Jazelle extension

ARMv8 requires that the implementation of AArch32 state includes the trivial Jazelle implementation.

A trivial implementation of the Jazelle extension must:

- Implement the [JIDR](#) with the implementer and subarchitecture fields set to zero. The register can be implemented so that the whole register is RAZ.
- Implement the [JMCR](#) as RAZ/WI.

- Implement the [JOSCR](#) either:
  - So that it can be read and written, but its effects are ignored.
  - As RAZ/WI.This ensures that operating systems that support an EJVM execute correctly.
- Implement the BXJ instruction to behave identically to the BX instruction in all circumstances, as required by the fact that the [JMCR.JE](#) bit is always zero. This means that, with a trivial implementation of the Jazelle extension, Jazelle state can never be entered normally.
- Treat Jazelle state as an unimplemented instruction set state, as described in [Exception return to an unimplemented instruction set state on page G1-3458](#).

A trivial implementation does not have to extend the PC to 32 bits, that is, it can implement PC[0] as RAZ/WI. This is because the only way that PC[0] is visible in A32 or T32 state is as a result of an exception occurring during Jazelle state execution, and Jazelle state execution cannot occur on a trivial implementation.

## G1.11 Handling exceptions that are taken to an Exception level using AArch32

An exception causes the PE to suspend program execution to handle an event, such as an externally generated interrupt or an attempt to execute an undefined instruction. Exceptions can be generated by internal and external sources.

Normally, when an exception is taken the PE state is preserved immediately, before handling the exception. This means that, when the event has been handled, the original state can be restored and program execution resumed from the point where the exception was taken.

More than one exception might be generated at the same time, and a new exception can be generated while the PE is handling an exception.

The following sections describe exception handling:

- [Exception vectors and the exception base address.](#)
- [Exception priority order on page G1-3435.](#)
- [Overview of exception entry on page G1-3436.](#)
- [PE mode for taking exceptions on page G1-3439.](#)
- [PE state on exception entry on page G1-3450.](#)
- [Routing general exceptions to EL2 on page G1-3452.](#)
- [Routing Debug exceptions to Hyp mode on page G1-3454.](#)
- [Exception return to an Exception level using AArch32 on page G1-3454.](#)
- [Wait For Event and Send Event on page G1-3460.](#)
- [Wait For Interrupt on page G1-3463.](#)

[Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3465](#) gives a full description of asynchronous exception handling, for exceptions taken asynchronously from AArch32 state.

### ———— **Note** —————

Because of the common model for handling exceptions, the current section requires some understanding of the asynchronous exception behaviors described in [Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3465](#).

[AArch32 state exception descriptions on page G1-3475](#) then describes each exception.

### G1.11.1 Exception vectors and the exception base address

When an exception is taken, PE execution is forced to an address that corresponds to the type of exception. This address is called the *exception vector* for that exception. The vectors for the different types of exception form a *vector table*.

### ———— **Note** —————

There are significant differences in the sets of exception vectors for exceptions taken to an Exception level that is using AArch32 and for exceptions taken to an Exception level that is using AArch64. This part of this manual describes only how exceptions are taken to an Exception level that is using AArch32. So, for example, when executing at EL1 or EL0, an exception might be generated that must be taken to EL3. In this case:

- If EL3 is using AArch32 then the exception is taken as described in this chapter, using the exception vectors described in this section.
- If EL3 is using AArch64 then the exception is taken as described in [Chapter D1 The AArch64 System Level Programmers' Model](#) using the exception vectors described in [Exception vectors on page D1-1430](#).

AArch32 state defines exception vector tables for exceptions taken to EL2 and EL3 when those Exception levels are using AArch32. Those vector tables are not used when the corresponding Exception levels are using AArch64.

A set of exception vectors for an Exception level that is using AArch32 comprises eight consecutive word-aligned memory addresses, starting at an *exception base address*. These eight vectors form an AArch32 *vector table*.

The number of possible exception base addresses, and therefore the number of vector tables, depends on the implemented Exception levels, as follows:

### Implementation that does not include EL3

Any implementation that does not include EL3 must include the following AArch32 vector table if EL1 can use AArch32:

- An exception table for exceptions taken to EL1 modes other than System mode. This is the EL1 vector table, and is in the address space of the PL1&0 translation regime.

———— **Note** —————

Exceptions cannot be taken to System mode.

For this vector table, the **VBAR** holds the exception base address.

### Implementation that includes EL2

Any implementation that includes EL2 must include the following additional AArch32 vector table if EL2 can use AArch32:

- An exception table for exceptions taken to Hyp mode. This is the Hyp vector table, and is in the address space of the Non-secure PL2 translation regime.

For this vector table, **HVBAR** holds the exception base address.

### Implementation that includes EL3

Any implementation that includes EL3 must include the following AArch32 vector tables:

- If EL3 can use AArch32, a vector table for exceptions taken to Secure Monitor mode. This is the Monitor vector table, and is in the address space of the Secure PL1&0 translation regime.

For this vector table, **MVBAR** holds the exception base address.

- If Secure EL1 can use AArch32, a vector table for exceptions taken to Secure privileged modes other than Monitor mode and System mode. This is the Secure vector table, and is in the address space of the Secure PL1&0 translation regime.

For this vector table, the Secure **VBAR** holds the exception base address.

- If Non-secure EL1 can use AArch32, a vector table for exceptions taken to Non-secure PL1 modes. This is the Non-secure vector table, and is in the address space of the Non-secure PL1&0 translation regime.

For this vector table, the Non-secure **VBAR** holds the exception base address.

The following subsections give more information:

- [The vector tables and exception offsets.](#)
- [Pseudocode determination of the exception base address on page G1-3434.](#)

### The vector tables and exception offsets

Table G1-3 on page G1-3433 defines the AArch32 vector table entries. In this table:

- The *Hyp mode* column defines the vector table entries for exceptions taken to Hyp mode.
- The *Monitor mode* column defines the vector table entries for exceptions taken to Monitor mode.
- The *Secure* and *Non-secure* columns define the Secure and Non-secure vector table entries, that are used for exceptions taken to modes other than Monitor mode, Hyp mode, System mode, and User mode. Table G1-4 on page G1-3433 shows the mode to which each of these exceptions is taken. Each of these modes is described as the *default* mode for taking the corresponding exception.

———— **Note** —————

Exceptions cannot be taken to System mode or User mode.

For more information about determining the mode to which an exception is taken, see *PE mode for taking exceptions* on page G1-3439.

When EL2 is using AArch3, it provides a number of additional exceptions, some of which are not shown explicitly in the vector tables. For more information, see *Offsets of AArch32 exceptions provided by EL2*.

**Table G1-3 The AArch32 vector tables**

Offset	Vector tables			
	Hyp <sup>a</sup>	Monitor <sup>b</sup>	Secure <sup>c</sup>	Non-secure <sup>c</sup>
0x00	Not used	Not used	Reset	Not used
0x04	Undefined Instruction, from Hyp mode	Not used	Undefined Instruction	Undefined Instruction
0x08	Hypervisor Call, from Hyp mode	Secure Monitor Call	Supervisor Call	Supervisor Call
0x0C	Prefetch Abort, from Hyp mode	Prefetch Abort	Prefetch Abort	Prefetch Abort
0x10	Data Abort, from Hyp mode	Data Abort	Data Abort	Data Abort
0x14	Hyp Trap, or Hyp mode entry <sup>d</sup>	Not used	Not used	Not used
0x18	IRQ interrupt	IRQ interrupt	IRQ interrupt	IRQ interrupt
0x1C	FIQ interrupt	FIQ interrupt	FIQ interrupt	FIQ interrupt

- a. Non-secure state only. Implemented only if the implementation includes EL2 and EL2 can use AArch32.
- b. Secure state only. Implemented only if the implementation includes EL3 and EL3 can use AArch32.
- c. If the implementation does not include EL3 then there is a single vector table for exceptions taken to EL1 when EL1 is using AArch32. That table holds the vectors shown in the Secure column of this table
- d. See *Use of offset 0x14 in the Hyp vector table* on page G1-3434.

**Table G1-4 Modes for taking the exceptions shown in the Secure or Non-secure vector table**

Exception	Mode taken to
Reset	Supervisor
Undefined Instruction	Undefined
Supervisor Call	Supervisor
Prefetch Abort	Abort
Data Abort	Abort
IRQ interrupt	IRQ
FIQ interrupt	FIQ

For more information about use of the vector tables see *Overview of exception entry* on page G1-3436.

**Offsets of AArch32 exceptions provided by EL2**

EL2 provides the following exceptions. When EL2 is using AArch32, these exceptions are taken to Hyp mode, and the PE enters the handlers for these exceptions using the following vector table entries shown in [Table G1-3](#):

**Hypervisor Call**

If taken from Hyp mode, shown explicitly in the Hyp mode vector table. Otherwise, see *Use of offset 0x14 in the Hyp vector table* on page G1-3434.

**Hyp Trap** Shown explicitly in the Hyp mode vector table.

**Virtual Abort** Entered through the Data Abort vector in the Non-secure vector table.

**Virtual IRQ** Entered through the IRQ vector in the Non-secure vector table.

**Virtual FIQ** Entered through the FIQ vector in the Non-secure vector table.

———— **Note** —————

*Virtual exceptions when an implementation includes EL2 on page G1-3465* gives more information about the virtual exceptions.

**Use of offset 0x14 in the Hyp vector table**

The vector at offset 0x14 in the Hyp vector table is used for exceptions that cause entry to Hyp mode. This means it is:

- Always used for the Hyp Trap exception.
- Used for any Hypervisor Call exception that is taken from a mode other than Hyp mode.
- Used for any Supervisor Call exception that is taken from Non-secure User mode when the value of [HCR.TGE](#) is 1.
- Used for any Undefined Instruction that is taken from Hyp mode, or is taken from Non-secure User mode when the value of [HCR.TGE](#) is 1.
- Used for any Prefetch Abort exception that is:
  - Taken from Non-secure User mode when the value of [HCR.TGE](#) is 1.
  - Generated by a Debug exception from Non-secure state when the value of [HDCR.TGE](#) is 1.
  - Generated by a stage 2 abort on an address translation operation.
- Used for any Data Abort exception that is:
  - Taken from Non-secure User mode when the value of [HCR.TGE](#) is 1.
  - Generated by an asynchronous External abort from Non-secure state when the value of [HCR.AMO](#) is 1.
  - Generated by a Debug exception from Non-secure state when the value of [HDCR.TGE](#) is 1.
  - Generated by a stage 2 abort on an address translation operation.

———— **Note** —————

Offset 0x14 is never used for IRQ exceptions, Virtual IRQ exceptions, FIQ exceptions, or Virtual FIQ exceptions.

For more information, see [PE mode for taking exceptions on page G1-3439](#).

**Pseudocode determination of the exception base address**

For an exception taken to a PL1 mode, the `ExcVectorBase()` function determines the exception base address:

```
// ExcVectorBase()
// =====

bits(32) ExcVectorBase()
    if SCTL.R.V == '1' then // Hivecs selected, base = 0xFFFFF000
        return Ones(16):Zeros(16);
    else
        return VBAR;
```

———— **Note** —————

The PL1 modes to which exceptions can be taken are Supervisor mode, Undefined mode, Abort mode, IRQ mode, and FIQ mode. In Non-secure state, and in Secure state when EL3 is using AArch64, these are EL1 modes. However, in Secure state when EL3 is using AArch32, these are EL3 modes. For more information see [Execution privilege, Exception levels, and AArch32 Privilege levels on page G3-3560](#).

## G1.11.2 Exception priority order

An instruction is not valid if it generates a synchronous Prefetch Abort exception. Therefore, if an instruction generates a synchronous Prefetch Abort exception, no other synchronous exception or debug event is generated on that instruction.

A Breakpoint debug event, or an address matching form of the Vector catch debug event, is associated with the instruction. This means the corresponding exception is taken before the instruction is executed. Therefore, when a Breakpoint or address matching Vector catch debug event occurs, no other synchronous exception or debug event, that might have occurred as a result of executing the instruction, can occur.

———— **Note** —————

An Exception Trapping Vector Catch exception is generated as a result of trapping an exception that has been prioritized as described in this section. This means it is outside the scope of the description in this section. For more information see [Breakpoint debug events and Vector Catch exception on page H2-4333](#).

Otherwise:

- An instruction that generates an Undefined Instruction exception or a Hyp Trap exception cannot cause any memory access, and therefore cannot cause a Data Abort exception.
- If an instruction generates both an Undefined Instruction exception and a Hyp Trap exception then, unless this manual explicitly states otherwise, the Undefined Instruction exception has priority.
- If a system call is configured to generate an Undefined Instruction exception or a Hyp Trap exception, then the Undefined Instruction exception or the Hyp Trap exception has priority over the system call.  
The system calls are the SVC, HVC, and SMC instructions.
- A memory access that generates fault on a stage of address translation or a synchronous Watchpoint debug event must not generate an external abort.
- All other synchronous exceptions are mutually exclusive and are derived from a decode of the instruction.

For more information, see:

- [Debug state entry and debug event prioritization on page H2-4331](#) for information about the prioritization of debug events, including their prioritization relative to a fault on a stage of address translation and synchronous external aborts
- [Prioritization of aborts on page G3-3658](#), for information about:
  - The prioritization of aborts on a single memory access in a VMSA implementation.
  - The prioritization of exceptions generated during address translation

## Architectural requirements for taking asynchronous exceptions

The ARM architecture does not define when asynchronous exceptions are taken, but sets the following limits on when they are taken:

- An asynchronous exception that is pending before one of the following context synchronizing events is taken before the first instruction after the context synchronizing event completes its execution, provided that the pending asynchronous event is not masked after the context synchronizing event. The context synchronizing events are:
  - Execution of an ISB instruction.
  - Taking an exception.
  - Return from an exception.
  - Exit from Debug state.

The [ISR](#) identifies any pending asynchronous exceptions.

———— **Note** —————

If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define the order in which that synchronous exception and the asynchronous exception are taken.

- In the absence of a specific requirement to take an asynchronous exception because of a context synchronizing event, the only requirement of the architecture is that an unmasked asynchronous exception is taken in finite time.

———— **Note** —————

The taking of an unmasked asynchronous exception in finite time must occur with all code sequences, including with a sequence that consists of unconditional loops.

Within these limits, the prioritization of asynchronous exceptions relative to other exceptions, both synchronous and asynchronous, is IMPLEMENTATION DEFINED.

The [CPSR](#) includes a mask bit for each type of asynchronous exception. Setting one of these bits to 1 can prevent the corresponding asynchronous exception from being taken, although when the PE is in Non-secure state other controls can modify the effect of these bits. For more information, see [Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3465](#).

Taking an exception sets an exception-dependent subset of these mask bits.

———— **Note** —————

In some contexts, the [CPSR](#).{A, I, F} bits mask the taking of asynchronous exceptions. The way these are set on exception entry, described in [CPSR.{A, I, F, M} values on exception entry on page G1-3451](#), can prevent an exception handler being interrupted by an asynchronous exception.

### G1.11.3 Overview of exception entry

There are some significant differences between the handling of exceptions taken to Hyp mode and exceptions taken to other modes. Because Hyp mode is the EL2 mode, this means the following descriptions sometimes distinguish between the *EL2 mode* and the *non-EL2 modes*.

On taking an exception to an Exception level that is using AArch32:

1. The hardware determines the mode to which the exception must be taken, see [PE mode for taking exceptions on page G1-3439](#).

2. A link value, indicating the *preferred return address* for the exception, is saved. This is a possible return address for the exception handler, and depends on:
  - The exception type.
  - Whether the exception is taken to the EL2 mode or to a non-EL2 mode.
  - For some exceptions taken to non-EL2 modes, the instruction set state when the exception was taken.

Where the link value is saved depends on whether the exception is taken to the EL2 mode.  
For more information see [Link values saved on exception entry on page G1-3438](#).
3. The value of the **CPSR** is saved in the **SPSR** for the mode to which the exception must be taken. The value saved in **SPSR.IT[7:0]** is always correct for the preferred return address.
4. In an implementation that includes EL3, when EL3 is using AArch32:
  - If the exception taken from Monitor mode, **SCR.NS** is cleared to 0.
  - Otherwise, taking the exception leaves **SCR.NS** unchanged.

When EL3 is using AArch64, Monitor mode is not available.
5. The **CPSR** is updated with new context information for the exception handler. This includes:
  - Setting **CPSR.M** to the PE mode to which the exception is taken.
  - Setting the appropriate **CPSR** mask bits. This can disable the corresponding exceptions, preventing uncontrolled nesting of exception handlers.
  - Setting the instruction set state to the state required for exception entry.
  - Setting the endianness to the required value for exception entry.
  - Clearing the **CPSR.IT[7:0]** bits to 0.

For more information, see [PE state on exception entry on page G1-3450](#).
6. The appropriate exception vector is loaded into the PC, see [Exception vectors and the exception base address on page G1-3431](#).
7. Execution continues from the address held in the PC.

For an exception taken to a non-EL2 mode, on exception entry, the exception handler can use the SRS instruction to store the return state onto the stack of any mode at the same Exception level and in the same Security state, and can use the CPS instruction to change mode. For more information about the instructions, see [SRS \(T32\) on page F7-3060](#), [SRS \(A32\) on page F7-3062](#), [CPS \(T32\) on page F7-3034](#), and [CPS \(A32\) on page F7-3036](#).

Later sections of this chapter describe each of the possible exceptions, and each of these descriptions includes a pseudocode description of the PE state changes on taking that exception. [Table G1-5](#) gives an index to these descriptions:

**Table G1-5 Pseudocode descriptions of exception entry for exceptions taken to AArch32 state**

Exception	Description of exception entry
Reset	<a href="#">Pseudocode description of taking the Reset exception on page G1-3476</a>
Undefined Instruction	<a href="#">Pseudocode description of taking the Undefined Instruction exception on page G1-3477</a>
Supervisor Call	<a href="#">Pseudocode description of taking the Supervisor Call exception on page G1-3479</a>
Secure Monitor Call	<a href="#">Pseudocode description of taking the Secure Monitor Call exception on page G1-3480</a>
Hypervisor Call	<a href="#">Pseudocode description of taking the Hypervisor Call exception on page G1-3481</a>
Prefetch Abort	<a href="#">Pseudocode description of taking the Prefetch Abort exception on page G1-3482</a>
Data Abort	<a href="#">Pseudocode description of taking the Data Abort exception on page G1-3484</a>
IRQ	<a href="#">Pseudocode description of taking the IRQ exception on page G1-3488</a>

**Table G1-5 Pseudocode descriptions of exception entry for exceptions taken to AArch32 state (continued)**

Exception	Description of exception entry
FIQ	<i>Pseudocode description of taking the FIQ exception on page G1-3489</i>
Hyp Trap	<i>Pseudocode description of taking the Hyp Trap exception on page G1-3479</i>
Virtual Abort	<i>Pseudocode description of taking the Virtual Asynchronous Abort exception on page G1-3486</i>
Virtual IRQ	<i>Pseudocode description of taking the Virtual IRQ exception on page G1-3489</i>
Virtual FIQ	<i>Pseudocode description of taking the Virtual FIQ exception on page G1-3490</i>

The following sections give more information about the PE state changes, for different architecture implementations. However, you must refer to the pseudocode for a full description of the state changes:

- *PE mode for taking exceptions on page G1-3439.*
- *PE state on exception entry on page G1-3450.*

### Link values saved on exception entry

On exception entry, a link value for use on return from the exception, is saved. This link value is based on the *preferred return address for the exception*, as shown in [Table G1-6](#):

**Table G1-6 Exception return addresses for exceptions taken to AArch32 state**

Exception	Preferred return address	Taken to a mode at
Undefined Instruction	Address of the UNDEFINED instruction	Non-EL2 <sup>a</sup> , or EL2 <sup>c</sup>
Supervisor Call	Address of the instruction after the SVC instruction	Non-EL2 <sup>a</sup> or EL2 <sup>c</sup>
Secure Monitor Call	Address of the instruction after the SMC instruction	EL3 <sup>b</sup> , and only in Secure state
Hypervisor Call	Address of the instruction after the HVC instruction	EL2 only <sup>c</sup>
Prefetch Abort	Address of aborted instruction fetch	Non-EL2 <sup>a</sup> or EL2 <sup>c</sup>
Data Abort	Address of instruction that generated the abort	Non-EL2 <sup>a</sup> or EL2 <sup>c</sup>
Virtual Abort	Address of next instruction to execute	EL1, and only in Non-secure state
Hyp Trap	Address of the trapped instruction	EL2 only <sup>c</sup>
IRQ or FIQ	Address of next instruction to execute	Non-EL2 <sup>a</sup> or EL2 <sup>c</sup>
Virtual IRQ or Virtual FIQ	Address of next instruction to execute	EL1, and only in Non-secure state

- EL1 if the exception is taken to a Non-secure mode, or is taken to a Secure mode when EL3 is using AArch64. EL3 if the exception is taken to a Secure mode when EL3 is using AArch64.
- A Secure Monitor Call exception is taken to EL3, and therefore is taken to AArch32 state only if EL3 is using AArch32, in which case it is taken to Monitor mode.
- EL2 is implemented only in Non-secure state. Therefore, an exception can be taken to EL2 mode only if it is taken from Non-secure state.

### Note

- Although Reset is described as an exception, it differs significantly from other exceptions. The architecture has no concept of a return from a Reset and therefore it is not listed in this section.
- For each exception, the preferred return address is not affected by the Exception level from which the exception was taken.

The link value saved, and where it is saved, depend on whether the exception is taken to a non-EL2 mode, or to a EL2 mode, as follows:

**Exception taken to a non-EL2 mode**

The link value is saved in the LR for the mode to which the exception is taken.

The saved link value is the preferred return address for the exception, plus an offset that depends on the instruction set state when the exception was taken, as [Table G1-7](#) shows:

**Table G1-7 Offsets applied to Link value for exceptions taken to EL1 modes**

Exception	Offset, for PE state of:	
	A32	T32 or T32EE
Undefined Instruction	+4	+2
Supervisor Call	None	None
Secure Monitor Call	None	None
Prefetch Abort	+4	+4
Data Abort	+8	+8
Virtual Abort	+8	+8
IRQ or FIQ	+4	+4
Virtual IRQ or Virtual FIQ	+4	+4

**Exception taken to a EL2 mode**

The link value is saved in the [ELR\\_hyp](#) Special register.

The saved link value is the preferred return address for the exception, as shown in [Table G1-6 on page G1-3438](#), with no offset.

**G1.11.4 PE mode for taking exceptions**

The following principles determine the Exception level to which an exception is taken, and if that Exception level is using AArch32, the PE mode to which the exception is taken:

- An exception cannot be taken to the EL0 mode.
- An exception is taken either:
  - To the Exception level at which the PE was executing when it took the exception.
  - To a higher Exception level.

This means that, in Secure state:

- When EL3 is using AArch32, an exception is always taken to an EL3 mode.
- When EL3 is using AArch64, an exception that is taken to AArch32 state is taken to an EL1 mode.
- Configuration options and other features provided by EL2 and EL3 can determine the mode to which some exceptions are taken, as follows:

**In an implementation that does not include EL2 or EL3**

An exception is always taken to the default mode for that exception.

### In an implementation that includes EL3

A Secure Monitor Call exception is always taken to EL3. This means:

- If EL3 is using AArch32 the exception is taken to Secure Monitor mode.
- If EL3 is using AArch64 then executing the instruction generates an exception that is taken to EL3, see *Execution of an SMC instruction from a privileged Exception level that is using AArch32* on page G1-3441.

IRQ, FIQ, and External abort exceptions can be configured to be taken to EL3. Therefore, if EL3 is using AArch32 the exceptions are taken to Secure Monitor mode.

Any exception taken from Secure state that is not taken to Secure Monitor mode is taken to Secure state in the default mode for that exception. As described in *Execution privilege, Exception levels, and AArch32 Privilege levels* on page G3-3560, this means it is taken to:

- An EL3 mode other than Monitor mode if EL3 is using AArch32.
- An EL1 mode if EL3 is using AArch64.

If the implementation does not include EL2, any exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state to the default mode for that exception. The default mode will be an EL1 mode.

### In an implementation that includes EL2

An exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state and:

- If the exception is taken from Hyp mode then it is taken to Hyp mode.
- Otherwise, the exception is either taken to Hyp mode, as described in *Exceptions taken to Hyp mode* on page G1-3441, or taken to the default mode for the exception.

#### ————— Note —————

- Hyp mode is the EL2 mode. The other modes to which an exception can be taken in Non-secure state are EL1 modes.
- EL2 has no effect on the handling of exceptions taken from Secure state.

Table G1-4 on page G1-3433 shows the default mode to which each exception is taken.

*Asynchronous exception routing controls* on page G1-3467 describes the exception routing controls provided by EL2 and EL3.

*Routing of aborts taken to AArch32 state* on page G3-3647 gives more information about the modes to which memory aborts are taken.

*Summary of the possible modes for taking each exception* on page G1-3442 shows all modes to which each exception might be taken, in any implementation. That is, it applies to implementations:

- That include neither EL2 nor EL3.
- That include EL2 but not EL3
- That do not include EL2 but include EL3
- That include both EL2 and EL3.

## Exceptions taken to Hyp mode

In an implementation that includes EL2 and EL3, when EL2 is using AArch32:

- Any exception taken from Hyp mode, that is not routed to EL3 by the controls described in *Asynchronous exception routing controls* on page G1-3467, is taken to Hyp mode.
  - The following exceptions, if taken from Non-secure state, are taken to Hyp mode:
    - An abort that *Routing of aborts taken to AArch32 state* on page G3-3647 identifies as taken to Hyp mode.
    - A Hyp Trap exception, see *AArch32 control of traps to the hypervisor* on page G1-3503.
    - A Hypervisor Call exception. This is generated by executing a HVC instruction in a Non-secure mode.
    - An asynchronous abort, IRQ exception or FIQ exception that is not routed to EL3 but is explicitly routed to Hyp mode, as described in *Asynchronous exception routing controls* on page G1-3467.
    - A synchronous external abort, Alignment fault, Undefined Instruction exception, or Supervisor Call exception taken from the Non-secure EL0 mode and explicitly routed to Hyp mode, as described in *Routing general exceptions to EL2* on page G1-3452.
- **Note** ————
- A synchronous external abort can be routed to Hyp mode only if it is not routed to EL3.
- 
- A debug exception that is explicitly routed to Hyp mode as described in *Routing Debug exceptions to Hyp mode* on page G1-3454.

———— **Note** ————

The virtual exceptions cannot be taken to Hyp mode. They are always taken to a Non-secure EL1 mode.

————

## Security behavior in Exception levels using AArch32 when EL3 is using AArch64

As described in *The ARMv8-A security model* on page G1-3407, when EL3 is using AArch64, lower Exception levels, in either Security state, can be using AArch32. This means software executing in those Exception levels might try to access AArch32 security features that are not available. The following subsections describe the associated behaviors:

- *Execution of an SMC instruction from a privileged Exception level that is using AArch32*
- *Non-secure reads of the NSACR*
- *Secure EL1 operations when Secure EL1 is using AArch32* on page G1-3442

### ***Execution of an SMC instruction from a privileged Exception level that is using AArch32***

When EL3 is using AArch64, an SMC instruction executed from Secure or Non-secure EL1 using AArch32, or from Non-secure EL2 using AArch32 when the value of HCR.TSC is 0, generates an exception that is taken to EL3. The exception syndrome is reported with an EC value of 0x13, SMC instruction executed in AArch32 state, see *Exception from SMC instruction execution in AArch32 state* on page D1-1522.

### ***Non-secure reads of the NSACR***

The NSACR is defined as being RO from Non-secure PE modes other than User mode. When EL3 is using AArch64, a read of the NSACR returns a fixed value of 0x00000C00 in the following cases:

- If the read is from a Non-secure EL1 mode when EL1 is using AArch32.
- If the read is from Hyp mode when EL2 is using AArch32.

### Secure EL1 operations when Secure EL1 is using AArch32

When Secure EL1 is using AArch32 and EL3 is using AArch64:

- Any of the following operations performed in a Secure EL1 mode is trapped to Secure EL3:
  - A read or write of any of the [SCR](#), [NSACR](#), [MVBAR](#), and [SDCR](#).
  - Performing any of the [ATS12NSO\\*\\*](#) operations described in [Address translation stages 1 and 2, Non-secure state only](#) on page G3-3686.
  - Executing an SRS instruction that would use [SP\\_mon](#), see [SRS \(T32\) on page F7-3060](#) and [SRS \(T32\) on page F7-3060](#).
  - Executing a MRS (Banked register) or MSR (Banked register) instruction that would access [SPSR\\_mon](#), [SP\\_mon](#), or [LR\\_mon](#), see [MRS \(Banked register\) on page F7-3048](#) and [MSR \(Banked register\) on page F7-3050](#).

For more information about these traps, including the associated exception syndromes, see [Traps to EL3 of monitor functionality from Secure EL1 using AArch32 on page D1-1500](#).

- Writes to the [CNTFRQ](#) register are UNDEFINED.
- Any attempt to move into Monitor mode, either by an exception return or by executing a CPS or MSR instruction, is treated as an illegal operation and is handled as described in [Illegal exception returns to AArch32 state on page G1-3456](#).

#### ————— **Note** —————

This functionality supports a usage model where:

- EL3 uses AArch64.
- Secure software executed in Secure EL1 using AArch32 and Secure EL0 using AArch32.
- The Non-secure state uses AArch64.

### Summary of the possible modes for taking each exception

The following subsections describe the modes to which each exception can be taken:

- [Determining the PE mode to which the Undefined Instruction exception is taken on page G1-3443](#).
- [Determining the PE mode to which the Supervisor Call exception is taken on page G1-3444](#).
- [The PE mode to which the Secure Monitor Call exception is taken on page G1-3444](#).
- [The PE mode to which the Hypervisor Call exception is taken on page G1-3445](#).
- [The PE mode to which the Hyp Trap exception is taken on page G1-3445](#).
- [Determining the PE mode to which the Prefetch Abort exception is taken on page G1-3446](#).
- [Determining the PE mode to which the Data Abort exception is taken on page G1-3447](#).
- [The PE mode to which the Virtual Abort exception is taken on page G1-3448](#).
- [Determining the PE mode to which the physical IRQ exception is taken on page G1-3448](#).
- [The PE mode to which the Virtual IRQ exception is taken on page G1-3448](#).
- [Determining the PE mode to which the physical FIQ exception is taken on page G1-3449](#).
- [The PE mode to which the Virtual FIQ exception is taken on page G1-3449](#).

These descriptions also show the vector offset for the exception entry for each mode. These descriptions assume that all Exception levels are using AArch32, meaning:

- [HCR](#), rather than [HCR\\_EL2](#), controls the routing of exceptions to EL2.
- [SCR](#), rather than [SCR\\_EL3](#), controls the routing of exceptions to EL3.

For more information about:

- Vector offsets, see [Exception vectors and the exception base address on page G1-3431](#).
- The routing of external aborts, IRQ and FIQ exceptions, and the virtual exceptions, see [Asynchronous exception routing controls on page G1-3467](#).

**Determining the PE mode to which the Undefined Instruction exception is taken**

Figure G1-4 shows how the implementation, state, and configuration options determine the PE mode to which an Undefined Instruction exception is taken.

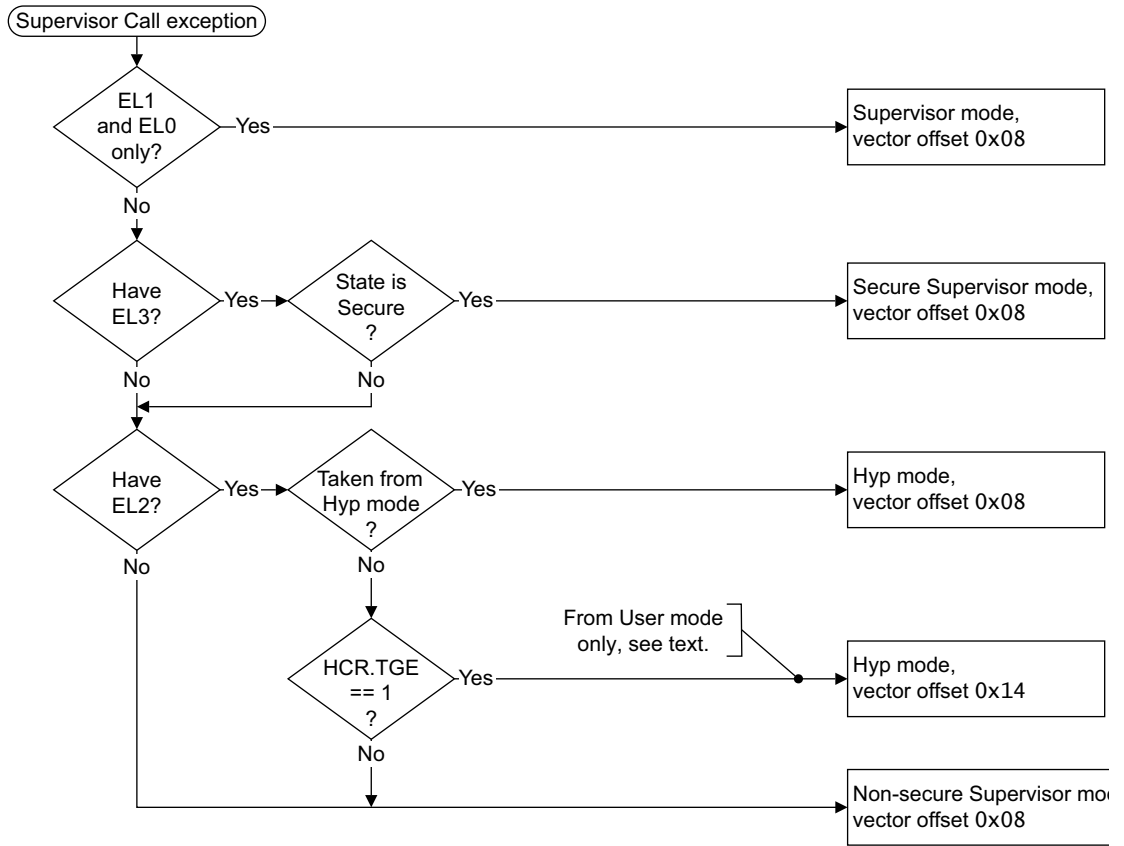

**Figure G1-4 The PE mode the Undefined Instruction exception is taken to**

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-3449.

**Determining the PE mode to which the Supervisor Call exception is taken**

Figure G1-5 shows how the implementation, state, and configuration options determine the PE mode to which a Supervisor Call exception is taken.

**Figure G1-5 The PE mode the Supervisor Call exception is taken to**

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-3449.

**The PE mode to which the Secure Monitor Call exception is taken**

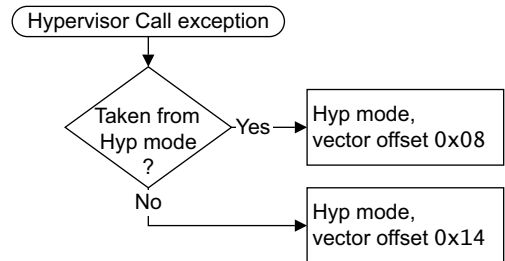

The Secure Monitor Call exception is supported only as part of EL3. When EL3 is using AArch32, a Secure Monitor Call exception is taken to Monitor mode, using vector offset 0x08 from the Monitor exception base address.

**Note**

- An SMC instruction that is trapped to Hyp mode because HCR.TSC is set to 1 generates a Hyp Trap exception, see *The PE mode to which the Hyp Trap exception is taken* on page G1-3445.
- If EL3 is using AArch64 then *Security behavior in Exception levels using AArch32 when EL3 is using AArch64* on page G1-3441 describes the effect of executing an SMC instruction in a mode that is part of an Exception level that is using EL1.

**The PE mode to which the Hypervisor Call exception is taken**

The Hypervisor Call exception is supported only as part of EL2. When EL2 is using AArch32, a Hypervisor Call exception is taken to Hyp mode, using a vector offset that depends on the mode from which the exception is taken, as Figure G1-6 shows. This offset is from the Hyp exception base address.

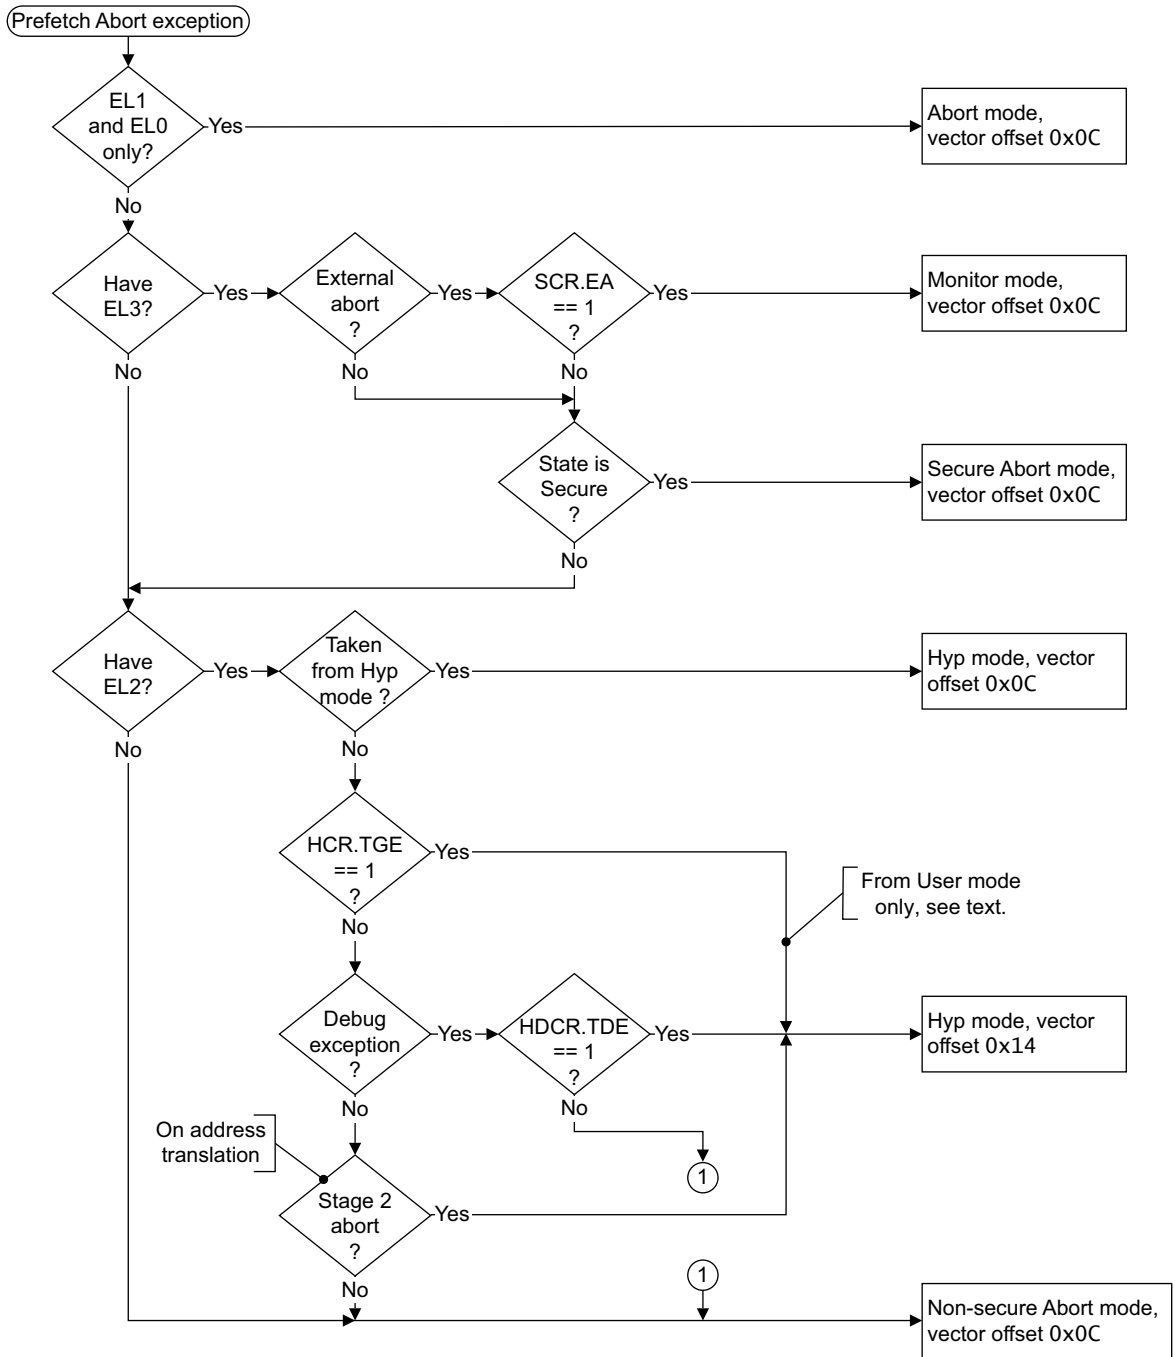

**Figure G1-6 The PE mode the Hypervisor Call exception is taken to**

**The PE mode to which the Hyp Trap exception is taken**

The Hyp Trap exception is supported only as part of EL2. When EL2 is using AArch32, a Hyp Trap exception is taken to Hyp mode, using a vector offset of 0x14 from the Hyp exception base address.

**Determining the PE mode to which the Prefetch Abort exception is taken**

Figure G1-7 shows how the implementation, state, and configuration options determine the PE mode to which a Prefetch Abort exception is taken.

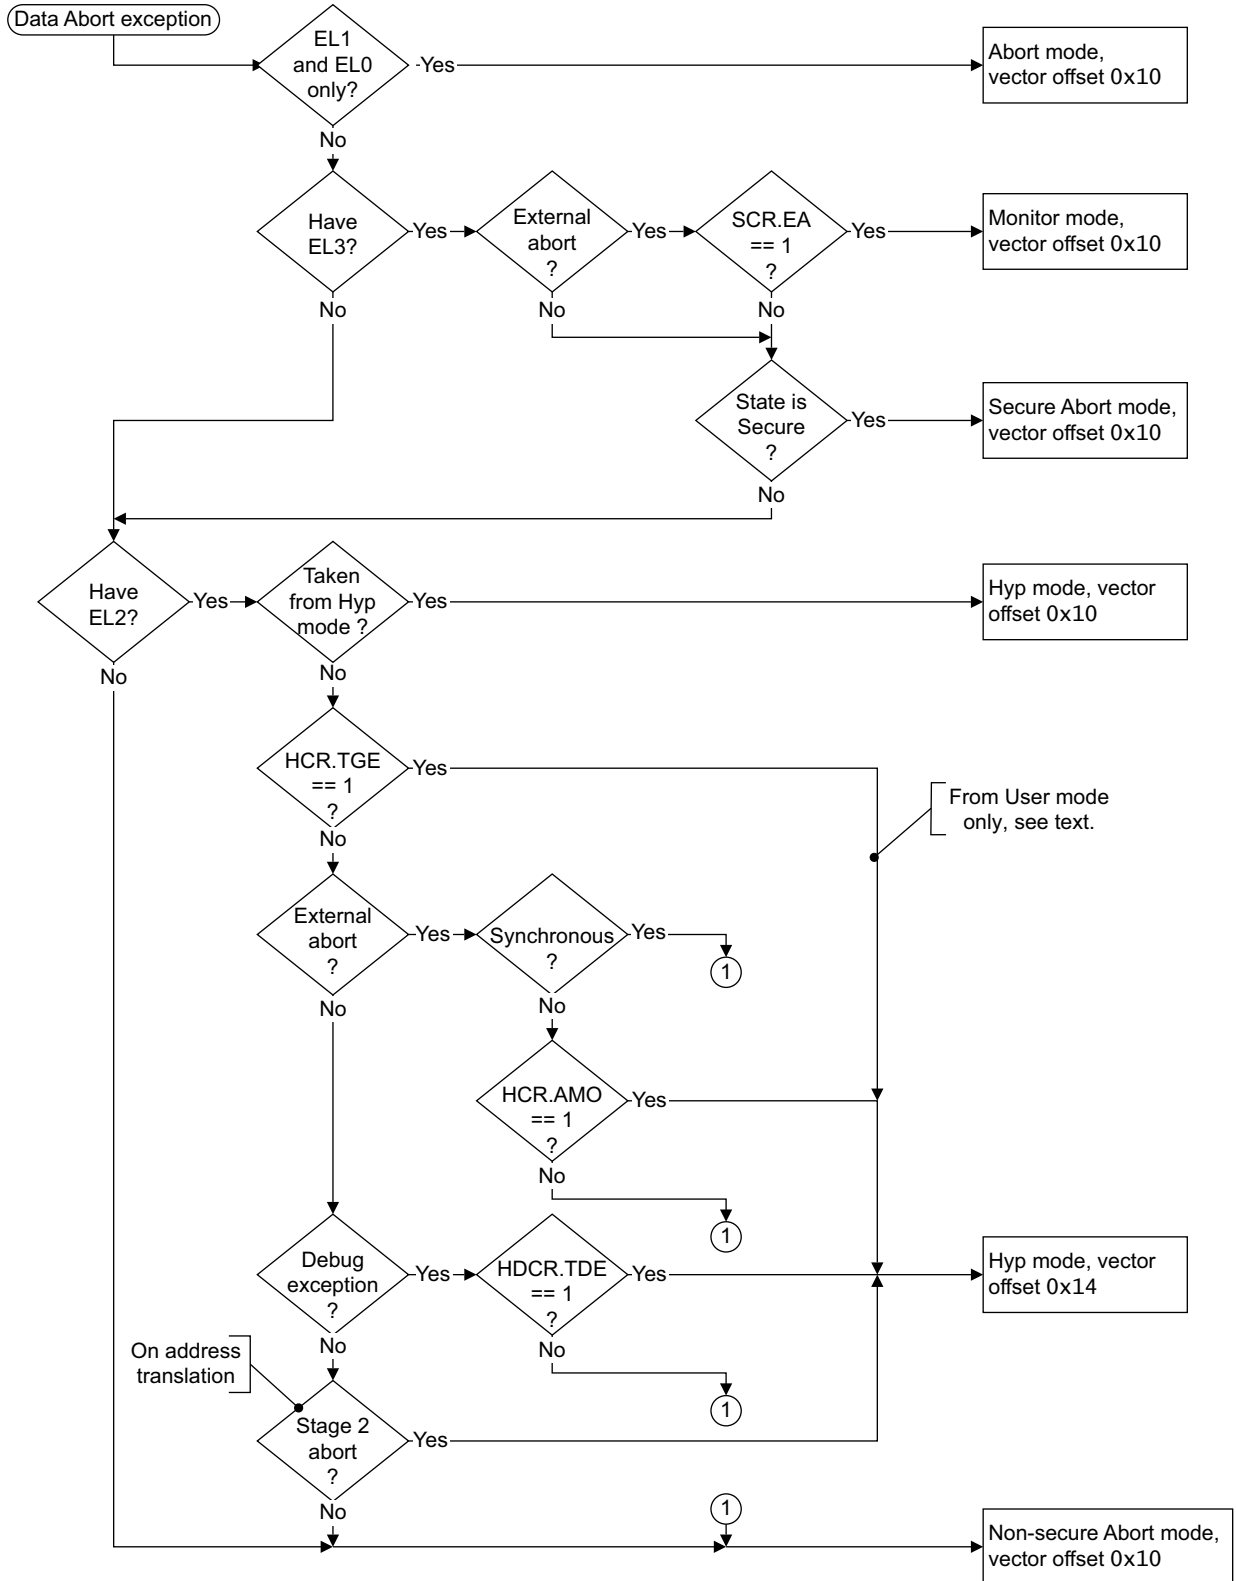

**Figure G1-7 The PE mode the Prefetch Abort exception is taken to**

See also *UNPREDICTABLE* cases when the value of *HCR.TGE* is 1 on page G1-3449.

**Determining the PE mode to which the Data Abort exception is taken**

Figure G1-8 shows the determination of the mode to which a Data Abort exception is taken.

**Figure G1-8 The PE mode the Data Abort exception is taken to**

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-3449.

**The PE mode to which the Virtual Abort exception is taken**

The Virtual Abort exception is supported only as part of EL2. A Virtual Abort exception is taken from a Non-secure EL1 or EL0 mode, and is taken to Non-secure Abort mode, using a vector offset of 0x10 from the Non-secure exception base address.

For more information about this exception see *Virtual exceptions when an implementation includes EL2* on page G1-3465.

**Determining the PE mode to which the physical IRQ exception is taken**

Figure G1-9 shows how the implementation, state, and configuration options determine the mode to which an IRQ exception is taken.

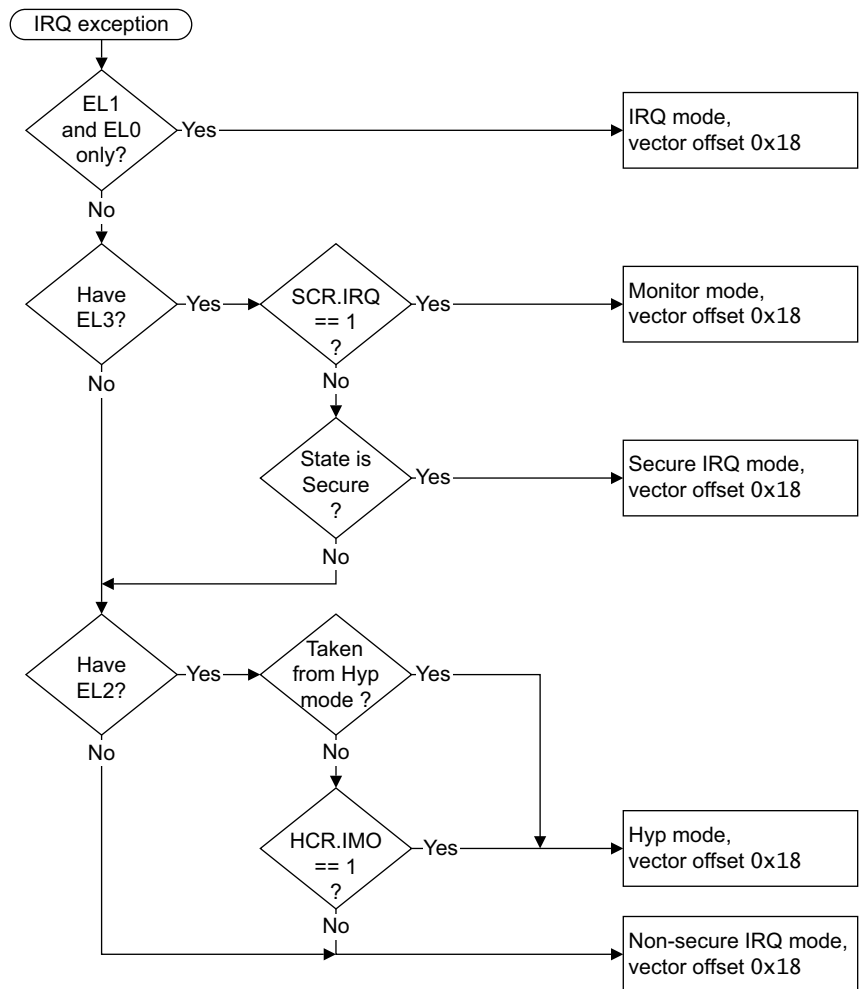

Figure G1-9 The PE mode the IRQ exception is taken to

**The PE mode to which the Virtual IRQ exception is taken**

The Virtual IRQ exception is supported only as part of EL2. A Virtual IRQ exception is taken from a Non-secure EL1 or EL0 mode, and is taken to Non-secure IRQ mode, using a vector offset of 0x18 from the Non-secure exception base address.

For more information about this exception see *Virtual exceptions when an implementation includes EL2* on page G1-3465.

**Determining the PE mode to which the physical FIQ exception is taken**

Figure G1-9 on page G1-3448 shows how the implementation, state, and configuration options determine the PE mode to which an FIQ exception is taken.

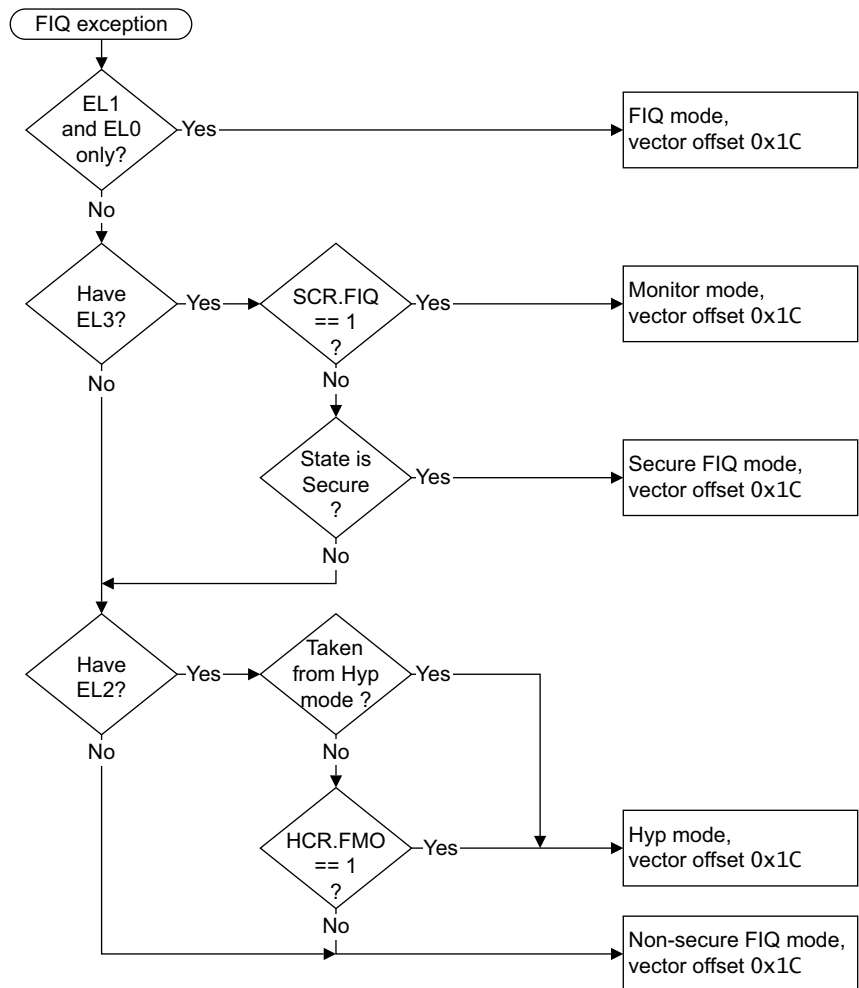

Figure G1-10 The PE mode the FIQ exception is taken to

**The PE mode to which the Virtual FIQ exception is taken**

The Virtual FIQ exception is supported only as part of EL2. A Virtual FIQ exception is taken from a Non-secure EL1 or EL0 mode, and is taken to Non-secure FIQ mode, using a vector offset of 0x1C from the Non-secure exception base address.

For more information about this exception see [Virtual exceptions when an implementation includes EL2](#) on page G1-3465.

**UNPREDICTABLE cases when the value of HCR.TGE is 1**

When the value of HCR.TGE is 1, exceptions that would otherwise be taken to EL1 are, instead, routed to EL2, see [Routing general exceptions to EL2](#) on page G1-3452. Related to this, when the value of HCR.TGE is 1, execution in a Non-secure EL1 mode is UNPREDICTABLE. ARMv8 does not constrain this UNPREDICTABLE behavior, but in ARMv8 software that follows the ARM recommendations cannot get to this state. When following the ARM recommendations, any attempt to move to a Non-secure EL1 mode when the value of HCR.TGE is 1 is either:

- An illegal exception return, see [Illegal exception returns to AArch32 state](#) on page G1-3456.
- An illegal PE mode change, see [Illegal changes to the CPSR.M field](#) on page G1-3458.

### G1.11.5 PE state on exception entry

The description of each exception includes a pseudocode description of entry to that exception, as [Table G1-5 on page G1-3437](#) shows. The following sections describe the PE state changes on entering an exception, for different implementations and operating states. However, you must always see the exception entry pseudocode for a full description of the state changes on exception entry:

- [Instruction set state on exception entry.](#)
- [CPSR.E bit value on exception entry.](#)
- [CPSR.{A, I, F, M} values on exception entry on page G1-3451.](#)

———— **Note** —————

The descriptions in these sections assume that EL2 and EL3, that control some aspects of the routing of exceptions taken from EL1 or EL0, are both using AArch32. If this is not the case:

- If EL2 is using AArch64:
  - Controls shown as provided by the [HSCTLR](#) are provided by the [SCTLR\\_EL2](#).
  - Controls shown as provided by the [HCR](#) are provided by the [HCR\\_EL2](#).
- If EL3 is using AArch64, controls shown as provided by the [SCR](#) are provided by the [SCR\\_EL3](#).

#### Instruction set state on exception entry

Exception handlers can execute in either T32 state or A32 state. On exception entry, the [CPSR.{T, J}](#) are set to the required values, with the [CPSR.T](#) value determined by [SCTLR.TE](#) or [HSCTLR.TE](#), depending on the mode the exception is taken to. [Table G1-8](#) shows this:

**Table G1-8 CPSR.{J, T} bit values on exception entry**

Exception mode	HSCTLR.TE	SCTLR.TE	CPSR.J	CPSR.T	Exception handler state
Not Hyp	x	0	0	0	A32
		1	0	1	T32
Hyp	0	x	0	0	A32
		x	0	1	T32

When an implementation includes EL3 and EL3 is using AArch32, [SCTLR](#) is Banked for Secure and Non-secure states, and therefore the TE bit value might be different for Secure and Non-secure states. For an exception taken to a Secure or Non-secure non-Hyp mode, the [SCTLR.TE](#) bit for the Security state to which the exception is taken determines the instruction set state for the exception handler. This means the non-Hyp mode exception handlers might run in different instruction set states, depending on the Security state.

#### CPSR.E bit value on exception entry

The [CPSR.E](#) bit controls the load and store endianness for data handling. [Table G1-9](#) show the value to which this bit is set on exception entry:

**Table G1-9 CPSR.E bit value on exception entry**

Exception mode	HSCTLR.EE	SCTLR.EE	Endianness for data loads and stores	CPSR.E
Secure or Non-secure EL1	x	0	Little-endian	0
		1	Big-endian	1
Hyp	0	x	Little-endian	0
		x	Big-endian	1

For more information, see the bit description in *Format of the CPSR and SPSRs* on page G1-3423.

### CPSR.{A, I, F, M} values on exception entry

On exception entry, CPSR.M is set to the value for the mode to which the exception is taken, as described in *PE mode for taking exceptions* on page G1-3439.

Table G1-10 shows the cases where CPSR.{A, I, F} bits are set to 1 on an exception entry, and how this depends on the mode and Security state to which an exception is taken. If the table entry for a particular mode and Security state does not define a value for a CPSR.{A, I, F} bit then that bit is unchanged by the exception entry. In this table:

- The *Exception mode* column is the mode to which the exception is taken.
- The *Non-secure, EL2 not implemented* column applies to exceptions taken to Non-secure state in an implementation that includes EL3 but does not include EL2.
- The *All others* column applies to:
  - Exceptions taken to Secure state.
  - Implementations that do not include the EL3.
  - Exceptions taken to Non-secure state in an implementation that includes EL2.

**Table G1-10 CPSR.{A, I, F} values on exception entry**

PE mode exception is taken to	Security state	
	Non-secure	Secure
Hyp	If SCR.EA==0 then CPSR.A is set to 1 If SCR.IRQ==0 then CPSR.I is set to 1 If SCR.FIQ==0 then CPSR.F is set to 1	-
Monitor	-	CPSR.A is set to 1 CPSR.I is set to 1 CPSR.F is set to 1
FIQ	CPSR.A is set to 1 CPSR.I is set to 1 CPSR.F is set to 1	CPSR.A is set to 1 CPSR.I is set to 1 CPSR.F is set to 1
IRQ, Abort	CPSR.A is set to 1 CPSR.I is set to 1	CPSR.A is set to 1 CPSR.I is set to 1
Undefined, Supervisor	CPSR.I is set to 1	CPSR.I is set to 1

*Asynchronous exception behavior for exceptions taken from AArch32 state* on page G1-3465 describes how, in some situations, the CPSR.{A, I, F} bits mask the taking of asynchronous aborts, IRQ interrupts, and FIQ interrupts.

## G1.11.6 Routing general exceptions to EL2

### Note

The routing provided when the value of [HCR.TGE](#) is 1 permits a usage model where applications execute in User mode under a hypervisor, that executes in Hyp mode, without a Guest OS running in a Non-secure EL1 mode.

When the value of [HCR.TGE](#) is 1, and the PE is in Non-secure User mode, any exception that would otherwise be taken to EL1 is taken to EL2. If EL2 is using AArch32 this means it is taken to Hyp mode, instead of to the default Non-secure mode for handling the exception. This means that, when the value of [HCR.TGE](#) is 1 and EL2 is using AArch32, the following exceptions are taken from User mode to Hyp mode:

- Undefined Instruction exceptions.
- Supervisor Call exceptions.
- Prefetch Abort exceptions that are not routed to EL3.
- Data Abort exceptions that are not routed to EL3.

### Note

The only Prefetch Abort and Data Abort exceptions that might be routed to EL3 are those caused by an external abort. These are routed to EL3 when the value of [SCR.EA](#) is 1.

The following sections give more information about the behavior when each of these exceptions is routed in this way:

- *Undefined Instruction exception, when [HCR.TGE](#) is set to 1.*
- *Supervisor Call exception, when [HCR.TGE](#) is set to 1.*
- *External abort, when [HCR.TGE](#) is set to 1 on page G1-3453.*
- *MMU fault, when [HCR.TGE](#) is set to 1 on page G1-3453.*

When the value of [HCR.TGE](#) is 1:

- Each of the [HDCR](#).{TDE, TDA, TDRA, TDOSA} bits is treated as 0 for all purposes other than reading the [HDCR](#) register.
- If the value of the [SCR.NS](#) bit is 1, then:
  - The [SCTLR.M](#) bit is treated as 0 for all purposes other than reading the [SCTLR](#) register.
  - Each of the [HCR](#).{HCR.FMO, IMO, AMO} bits is treated as 1 for all purposes other than reading the [HCR](#) register
  - An exception return to EL1 is treated as an illegal exception return, see *Illegal exception returns to AArch32 state on page G1-3456.*
  - Any IMPLEMENTATION DEFINED mechanisms for signalling virtual interrupts are disabled.

### Undefined Instruction exception, when [HCR.TGE](#) is set to 1

When [HCR.TGE](#) is set to 1, if the PE is executing in Non-secure User mode and attempts to execute an UNDEFINED instruction, it takes the Hyp Trap exception, instead of an Undefined Instruction exception. On taking the Hyp Trap exception, the [HSR](#) reports an unknown reason for the exception, using the EC value 0x00. For more information see *Use of the [HSR](#) on page G3-3672.*

### Supervisor Call exception, when [HCR.TGE](#) is set to 1

When [HCR.TGE](#) is set to 1, if the PE executes an SVC instruction in Non-secure User mode, the Supervisor Call exception generated by the instruction is taken to Hyp mode.

The [HSR](#) reports that entry to Hyp mode was because of a Supervisor Call exception, and:

- If the SVC is unconditional, takes for the `imm16` value in the [HSR](#):
  - A zero-extended 8-bit immediate value for the T32 SVC instruction.

---

**Note**

The only T32 encoding for SVC is a 16-bit instruction encoding.

---

— The bottom 16 bits of the immediate value for the A32 SVC instruction.

- If the SVC is conditional, the imm16 value in the HSR is UNKNOWN.

If the SVC is conditional, the PE takes the exception only if the instruction passes its condition code check.

The HSR reports the exception as a Supervisor Call exception taken to Hyp mode, using the EC value 0x11. For more information, see *Use of the HSR on page G3-3672*.

---

**Note**

The effect of setting HCR.TGE to 1 is to route the Supervisor Call exception to Hyp mode, not to trap the execution of the SVC instruction. This means that the preferred return address for the exception, when routed to Hyp mode in this way, is the instruction after the SVC instruction.

---

### External abort, when HCR.TGE is set to 1

When the value of HCR.TGE is 1, and SCR.EA is set to 0, if the PE is executing in Non-secure User mode then any external abort generates an exception that is taken as a Hyp Trap exception. Where an attempt to execute an instruction causes a synchronous external abort, on taking the Hyp Trap exception, the HSR indicates whether a Data Abort exception or a Prefetch Abort exception caused the Hyp Trap exception entry, and presents a valid syndrome in the HSR.

---

**Note**

- When SCR.EA is set to 1, external aborts are routed to Secure Monitor mode, and this takes priority over the HCR.TGE routing. For more information, see *Asynchronous exception routing controls on page G1-3467*. The SCR.EA control described in that section applies to both synchronous and asynchronous external aborts.
- Any asynchronous external abort generates a Data Abort exception. Therefore, if an asynchronous external abort is routed to Hyp mode because the value of HCR.TGE is 1 the exception is reported as a Data Abort exception routed to Hyp mode.

---

For an external abort on an instruction fetch, if the instruction that causes this exception is conditional, the PE takes the exception only if the instruction passes its condition code check.

The HSR reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
- As a Data Abort exception routed to Hyp mode, using the EC value 0x24.

For more information about the exception reporting, see *Use of the HSR on page G3-3672*.

---

### MMU fault, when HCR.TGE is set to 1

When the value of HCR.TGE is 1, if the PE is executing in Non-secure User mode, this control applies to any MMU fault resulting from any memory access.

In these cases, the attempted access generates a Hyp Trap exception, instead of either:

- A Prefetch Abort exception if the MMU fault was on an instruction fetch.
- A Data Abort exception if the MMU fault was on a data access.

For an MMU fault on an instruction fetch, if the instruction that causes this exception is conditional, the PE takes the exception only if the instruction passes its condition code check.

The HSR reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
- As a Data Abort exception routed to Hyp mode, using the EC value 0x24.

For more information about the exception reporting, see [Use of the HSR on page G3-3672](#).

### G1.11.7 Routing Debug exceptions to Hyp mode

When the value of `HDCR.TDE` is 1, if the PE is executing in a Non-secure mode other than Hyp mode, any Debug exception is routed to Hyp mode. This means it generates a Hyp Trap exception. This applies to:

- Debug exceptions associated with instruction fetch, that would otherwise generate a Prefetch Abort exception. These are exceptions generated by the Breakpoint, BKPT instruction, and Vector catch debug events, see [Breakpoint debug events and Vector Catch exception on page H2-4333](#).
- Debug exceptions associated with data accesses, that would otherwise generate a Data Abort exception. These are exceptions generated by the Watchpoint debug event, see [Breakpoint and Watchpoint debug events on page H2-4330](#).

When the value of `HDCR.TDE` is 1, each of the `HDCR.{TDRA, TDOSA, TDA}` bits is treated as 1 for all purposes other than reading the `HDCR` register. See also [Permitted combinations of HDCR.{TDRA, TDOSA, TDA, TDE} bits on page G1-3515](#).

#### ———— Note —————

- A debug event generates a debug exception only when invasive debug is enabled and Monitor debug-mode is selected, see [Exception Catch debug event on page H3-4377](#). When self-hosted debug is selected, a debug event causes Debug state entry and cannot be trapped to Hyp mode.
- When `HDCR.TDE` is set to 1, the Hyp Trap exception is generated instead of the Prefetch Abort exception or Data Abort exception that is otherwise generated by the Debug exception.
- Debug exceptions, other than the exception on the BKPT instruction, are not permitted in Hyp mode.

When a Hyp Trap exception is generated because `HDCR.TDE` is set to 1, The `HSR` reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value `0x20`.
- As a Data Abort exception routed to Hyp mode, using the EC value `0x24`.

For more information see [Use of the HSR on page G3-3672](#).

### G1.11.8 Exception return to an Exception level using AArch32

In the ARM architecture, *exception return* to an Exception level that is using AArch32 requires the simultaneous restoration of the PC and `CPSR` to values that are consistent with the desired state of execution on returning from the exception. Typically, exception return involves returning to one of:

- The instruction after the instruction boundary at which an asynchronous exception was taken.
- The instruction following an SVC, SMC, or HMC instruction, for an exception generated by one of those instructions.
- The instruction that caused the exception, after the reason for the exception has been removed.
- The subsequent instruction, if the instruction that caused the exception has been emulated in the exception handler.

The ARM architecture defines a *preferred return address* for each exception other than Reset, see [Link values saved on exception entry on page G1-3438](#). The values of the `SPSR.IT[7:0]` bits generated on exception entry are always correct for this preferred return address, but might require adjustment by the exception handler if returning elsewhere.

In some cases, to calculate the appropriate preferred return address for a return to an Exception level that is using AArch32, a subtraction must be performed on the link value saved on taking the exception. The description of each exception includes any value that must be subtracted from the link value, and other information about the required exception return.

On an exception return, the **CPSR** takes either:

- The value loaded by the RFE instruction.
- If the exception return is not performed by executing an RFE instruction, the value of the current **SPSR** at the time of the exception return.

*Illegal exception returns to AArch32 state on page G1-3456* describes the behavior if the restored PE state would not be valid for the Exception level, PE mode, and Security state targeted by the exception return.

## Exception return instructions

The instructions that an exception handler can use to return from an exception depend on whether the exception was taken to a EL1 mode, or in a EL2 mode, see:

- *Return from an exception taken to a PE mode other than Hyp mode.*
- *Return from an exception taken to Hyp mode.*

### **Return from an exception taken to a PE mode other than Hyp mode**

For an exception taken to a PE mode other than Hyp mode, the ARM AArch32 architecture provides the following *exception return instructions*:

- Data-processing instructions with the S bit set and the PC as a destination, see *SUBS PC, LR and related instructions (T32) on page F7-3066* and *SUBS PC, LR and related instructions (A32) on page F7-3068*.

Typically:

- A return where no subtraction is required uses SUBS with an operand of 0, or the equivalent MOVN instruction.
- A return requiring subtraction uses SUBS with a nonzero operand.
- The RFE instruction, see *RFE on page F7-3056*. If a subtraction is required, typically it is performed before saving the LR value to memory.
- In A32 state, a form of the LDM instruction, see *LDM (exception return) on page F7-3042*. If a subtraction is required, typically it is performed before saving the LR value to memory.

### **Return from an exception taken to Hyp mode**

For an exception taken to Hyp mode, the ARM architecture provides the ERET instruction, see *ERET on page F7-3038*. An exception handler executing in Hyp mode must return using the ERET instruction.

Both Hyp mode and the ERET instruction are implemented only as part of EL2.

## Alignment of exception returns

The {J, T} bits of the value transferred to the **CPSR** by an exception return control the target instruction set of that return. The behavior of the hardware for exception returns for different values of the {J, T} bits is as follows:

- {J, T} == 00** The target instruction set state is A32 state. Bits[1:0] of the address transferred to the PC are ignored by the hardware.
- {J, T} == 01** The target instruction set state is T32 state:
  - Bit[0] of the address transferred to the PC is ignored by the hardware.
  - Bit[1] of the address transferred to the PC is part of the instruction address.
- {J, T} == 10** Reserved, see *Exception return to an unimplemented instruction set state on page G1-3458*.

———— **Note** ————

Before ARMv8, these values indicated Jazelle state as the target instruction set state. However, ARMv8 requires a trivial implementation of the Jazelle extension, and therefore Jazelle state is not implemented. For a description of the trivial Jazelle implementation see [Trivial implementation of the Jazelle extension on page G1-3429](#).

- {J, T} == 11** The target instruction set state is T32EE state. If T32EE state is implemented:
- Bit[0] of the address transferred to the PC is ignored by the hardware.
  - Bit[1] of the address transferred to the PC is part of the instruction address.

However, in ARMv8 implementation of T32EE state is OPTIONAL and deprecated See [Exception return to an unimplemented instruction set state on page G1-3458](#) for a description of the behavior if T32EE state is not implemented.

ARM deprecates any dependence on the requirements that the hardware ignores bits of the address. ARM recommends that the address transferred to the PC for an exception return is correctly aligned for the target instruction set.

After an exception entry other than Reset, the LR value has the correct alignment for the instruction set indicated by the [SPSR.{J, T}](#) bits. This means that if exception return instructions are used with the LR and [SPSR](#) values produced by such an exception entry, the only precaution software needs to take to ensure correct alignment is that any subtraction is of a multiple of four if returning to A32 state, or a multiple of two if returning to T32 state or to T32EE state if T32EE state is implemented.

## Illegal exception returns to AArch32 state

Throughout this section:

### Saved process state

Refers to any of:

- The state held in the [SPSR](#) for any exception return other than an exception return made by executing an RFE instruction in AArch32 state.
- The state held in memory that is to be restored to the [CPSR](#) by the execution of an RFE instruction in AArch32 state.
- The state held in the [DSPSR](#) on a debug state exit.

### Exception or debug return

Refers to any of:

- An exception return.
- Execution of a DRPS instruction in debug state
- Exit from debug state.

### Configured from reset

Indicates state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.

The ARMv8 architecture has a generic mechanism for handling exception returns to a mode or state that is illegal. This can occur as a result of any of the following situations:

- An exception or debug return where the Exception level being returned to is higher than the current Exception level.
- An exception or debug return to EL1, EL2 or EL3 where the Execution state specified in the saved process state is different from the Execution state used in the exception level being returned to, as determined by the [SCR\\_EL3.RW](#) or [HCR\\_EL2\\_EL2.RW](#) bits, or as configured from reset.

- An exception or debug return to EL0 where the Execution state specified in the saved process state is AArch64 and the target Execution state for EL1, as determined by the [SCR\\_EL3.RW](#) or [HCR\\_EL2\\_EL2.RW](#) bits or as configured from reset, is AArch32.
- An exception or debug return to an Exception level that is not implemented or not accessible, for example:
  - A return to EL2 when the value of [SCR.NS](#) for the Exception level being returned to is 0.
  - Any return to an Exception level that is not implemented.
- An exception or debug return from AArch32 state when the saved process state indicates a return to AArch64 EL0 execution.
- An exception or debug return to Non-secure EL1 when the value of the [HCR.TGE](#) bit is 1.
- In an implementation that includes support for T32EE state, an exception or debug return to an exception level using AArch32 when the values of the saved process state {T, J} bits is {1, 1} and the value of the [SCTLR.THREE](#) bit for the target exception level is 0.  
In an implementation that does not support for T32EE state, it is IMPLEMENTATION DEFINED whether:
  - An exception or debug return to an exception level using AArch32 when the values of the saved process state {T, J} bits is {1, 1} is an illegal exception return.
  - The saved process state J bit is treated as 0.See also [Exception return to an unimplemented instruction set state on page G1-3458](#).
- An exception or debug return to an Exception level using AArch64 when the value of the saved process state M[1] bit is 1.
- An exception or debug return to an Exception level using AArch32 when the value of the saved process state M field value is not a valid mode. [Table G1-2 on page G1-3412](#) shows the M value for each of the AArch32 PE modes.
- Debug state exit from EL0 using AArch64 to EL0 using AArch32.

In these cases:

- [PSTATE.IL](#) is set to 1, to indicate an illegal exception or debug return.
- If the exception or debug return is from an Exception level that is using AArch32, the attempted exception or debug return does not change the PE mode. This means the [CPSR.M](#) field is unchanged.
- If the exception or debug return is from an Exception level that is using AArch64, the attempted exception or debug return does not change any of the Exception level, the Execution state, and the current stack pointer selection.
- The SS bit is handled in the same way as any other exception or debug return, see [Software Step exceptions on page D2-1634](#).
- The [CPSR.{GE, N, Z, C, V, Q, A, I, F, E}](#) fields are copied from the saved process state in the [SPSR](#) for the PE mode in which the exception is handled.
- The [CPSR.{IT, T, J}](#) bits are each either:
  - Set to 0
  - Copied from the saved process state in the [SPSR](#) for the PE mode in which the exception is handled.The choice between these two options is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

———— **Note** —————

An illegal exception return from an Exception level that is using AArch64 is handled in AArch64 state and therefore is not considered here.

All aspects of the illegal exception or debug return, other than the effects described in this section, occur as they do for a legal exception return.

### Exception return to an unimplemented instruction set state

In AArch32 state, the `CPSR.{J, T}` bits identify the current Instruction set state. In an ARMv8 implementation:

**Jazelle state** Corresponds to the `{J, T}` values `{1, 0}`, and is never implemented, because ARMv8 requires a trivial Jazelle implementation.

**T32EE state** Corresponds to the `{J, T}` values `{1, 1}`. Support for T32EE state is OPTIONAL and deprecated.

An ARMv8 implementation does not normally attempt to enter an unimplemented instruction set state, because:

- The trivial Jazelle implementation means the BXJ instruction acts as a BX instruction.
- If the implementation does not include T32EE support, the ENTERX instruction is UNDEFINED.
- Normal exception entry and return preserves the instruction set state.

However, an exception return instruction might set `CPSR.{J, T}` to the values corresponding to an unimplemented instruction set state, see *Unimplemented instruction sets on page G1-3429*. This is most likely to happen because a faulty exception handler restores the wrong value to the `CPSR`.

If the PE attempts to execute an instruction while the `CPSR.{J, T}` bits indicate an unimplemented instruction set state, an Undefined Instruction exception is taken. This happens if either:

- The value of `CPSR.{J, T}` is `{1, 0}`, the encoding for Jazelle state in previous versions of the architecture.
- The value of `CPSR.{J, T}` is `{1, 1}` and the implementation does not support T32EE state.

The Undefined Instruction exception handler can detect the cause of this exception because on entry to the handler the `SPSR.{J, T}` bits indicate the unimplemented instruction set state. If the Undefined Instruction exception handler wants to return to a valid instruction set state it can change the values its exception return instruction writes to the `CPSR.{J, T}` bits.

If an exception return writes `CPSR.{J, T}` values that correspond to an unimplemented instruction set state, and also writes the address of an aborting memory location to the PC, it is IMPLEMENTATION DEFINED whether:

- The instruction fetch is attempted, and a Prefetch Abort exception is taken because the memory access aborts.
- An Undefined Instruction exception is taken, without the instruction being fetched.

If an exception return writes `CPSR.{J, T}` values that correspond to an unimplemented instruction set, the width of the instruction fetch is an IMPLEMENTATION DEFINED value that is 2 or 4 bytes.

An ARMv8 implementation that does not support the T32EE state can implement the J bits of the PSRs as RAZ/WI. On such an implementation, a return to an unimplemented instruction set state cannot occur.

### Illegal changes to the CPSR.M field

The `CPSR.M` field can be changed explicitly using an MSR or CPS instruction. Changing the M field to any of the following values is an illegal change to the `CPSR.M` field:

- Changing M to a value that [Table G1-2 on page G1-3412](#) does not show as allocated.
- Changing M to the value that corresponds to a PE mode that is not implemented or not accessible.

This includes:

- When executing in Secure EL1, changing M to the value for Monitor mode when EL3 is using AArch64.
- In an implementation that includes EL2, writing the value for Hyp mode to the M field from any PE mode other than Hyp mode.
- In an implementation that includes EL2, when EL2 is using AArch32 and the PE is in Hyp mode, changing M to the value for any mode other than Hyp mode.
- Changing M to a value that would cause an increase in Exception level.
- When executing in Non-secure state, changing M to the value for Monitor mode.

In the ARMv8 Architecture, when in AArch32 state, the IL process state bit is used to catch any illegal explicit change to the **CPSR.M** field using an MSR or CPS instruction. In AArch32 state, the effect of such an illegal change to the **CPSR.M** field is that:

1. The current PE mode remains unchanged.
2. The **PSTATE.IL** bit is set to 1.
3. Any attempt to execute any instruction generates an Illegal Execution state exception.

The Illegal Execution state exception is handled as described in *Illegal exception returns to AArch32 state on page G1-3456*.

———— **Note** —————

In ARMv7, the effect of an illegal change to the **CPSR.M** field is UNPREDICTABLE.

—————

### Legal exception returns that set **CPSR.IL** to 1

When a legal exception return to AArch32 would set the **CPSR.IL** bit to 1, either by copying this value from an **SPSR**, or by loading it from memory if the exception return was performed by executing an RFE instruction, then the **CPSR.{IT, T, J}** bits are each either:

- Set to 0.
- Copied from the **SPSR**, or loaded from memory if the exception return was performed by executing an RFE instruction.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. This means software must regard each value as being an UNKNOWN choice between the two permitted values.

The exception return sets the **PSTATE.IL** bit to 1. This means that any attempt to execute any instruction generates an Illegal Execution state exception, that is handled as described in *Illegal exception returns to AArch32 state on page G1-3456*.

### The Illegal Execution state exception

When the value of **PSTATE.IL** is 1, any attempt to execute any instruction generates an Illegal Execution state exception. In AArch32 state, the **PSTATE.IL** bit can be set to 1 by any of:

- An illegal exception return, as described in *Illegal exception returns to AArch32 state on page G1-3456*.
- An illegal change to **CPSR.M**, as described in *Illegal changes to the CPSR.M field on page G1-3458*.
- A legal exception return that would set **CPSR.IL** to 1, as described in *Legal exception returns that set CPSR.IL to 1*.

An Illegal Execution State exception is taken in the same way as an Undefined Instruction exception in the current Exception level. If the current Exception level is EL2 using AArch32, the **HSR** provides a syndrome for the exception, as follows:

- **HSR.EC** has the value 0xE.
- The **HSR.IL** bit is invalid, and is RES1.
- The **HSR.ISS** field is RES0.

An Illegal Execution State exception has priority over any other Undefined Instruction exception that might arise from instruction execution.

———— **Note** —————

This section only describes the handling of an Illegal Execution State exception that is taken to an Exception level that is using AArch32. *Illegal return events on page D1-1441* describes the cases where an Illegal Execution State exception is taken to an Exception level that is using AArch64.

—————

On taking an Illegal Execution State exception to an Exception level that is using AArch32:

1. The value of the `PSTATE.IL` bit, 1, is copied to the `SPSR.IL` bit for the PE mode to which the exception is taken.
2. The `PSTATE.IL` bit is cleared to 0.

### G1.11.9 Wait For Event and Send Event

The Wait For Event (WFE) mechanism permits a PE to request entry to a low-power state, and, if the request succeeds, to remain in that state until an event is generated by a Send Event operation, or another WFE wake-up event occurs. [Example G1-2](#) describes how a spinlock implementation might use this mechanism to save energy.

#### Example G1-2 Spinlock as an example of using Wait For Event and Send Event

---

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device it might need to add data received from the device to a queue. If another PE is removing data from the queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the lock has been released. It cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in [Synchronization and semaphores on page E2-2369](#).
- If the PE obtains the lock it performs its memory operation and releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. At this point it again attempts to obtain the lock.

A spin-lock mechanism is not ideal for all situations:

- In a low-power system the tight read loop is undesirable because it uses energy to no effect.
- In a multi-threaded implementation the execution of spin-locks by waiting threads can significantly degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock. In this situation, a PE that fails to obtain a lock can execute a Wait For Event instruction, WFE, to request entry to a low-power state. When a PE releases a lock, it must execute a Send Event instruction, SEV, causing any waiting PEs to wake up. Then, these PEs can attempt to gain the lock again.

---

EL2 provides a bit that traps to Hyp mode any attempt to enter a low-power state from a Non-secure EL1 or EL0 mode. For more information see [Trapping use of the WFI and WFE instructions on page G1-3511](#).

The architecture does not define the exact nature of the low power state, but the execution of a WFE instruction must not cause a loss of memory coherency.

———— **Note** ————

Although a complex operating system can contain thousands of distinct locks, the event sent by this mechanism does not indicate which lock has been released. If the event relates to a different lock, or if another PE acquires the lock more quickly, the PE fails to acquire the lock and can re-enter the low-power state waiting for the next event.

---

The Wait For Event system relies on hardware and software working together to achieve energy saving:

- The hardware provides the mechanism to enter the Wait For Event low-power state.
- The operating system software is responsible for issuing:
  - A Wait For Event instruction, to request entry to the low-power state, used in the example when waiting for a spin-lock.
  - A Send Event instruction, required in the example when releasing a spin-lock.

The mechanism depends on the interaction of:

- WFE wake-up events, see [WFE wake-up events](#).
- The Event Register, see [The Event Register](#).
- The Send Event instruction, see [The Send Event instruction on page G1-3462](#).
- The Wait For Event instruction, see [The Wait For Event instruction on page G1-3462](#).

## WFE wake-up events

The following events are *WFE wake-up events*:

- The execution of an SEV instruction on any PE in the system.
- A physical IRQ interrupt, unless masked by the [CPSR.I](#) bit.
- A physical FIQ interrupt, unless masked by the [CPSR.F](#) bit.
- A physical asynchronous abort, unless masked by the [CPSR.A](#) bit.
- In Non-secure state in any mode other than Hyp mode:
  - When [HCR.IMO](#) is set to 1, a virtual IRQ interrupt, unless masked by the [CPSR.I](#) bit.
  - When [HCR.FMO](#) is set to 1, a virtual FIQ interrupt, unless masked by the [CPSR.F](#) bit.
  - When [HCR.AMO](#) is set to 1, a virtual asynchronous abort, unless masked by the [CPSR.A](#) bit.
- An asynchronous debug event, if invasive debug is enabled and the debug event is permitted.
- An event sent by the timer event stream, see [Event streams on page D7-1859](#).
- An event sent by some IMPLEMENTATION DEFINED mechanism.

In addition to the possible masking of WFE wake-up events shown in this list, when invasive debug is enabled and [DBGDSCRint\[15:14\]](#) is not set to 0b00, [DBGDSCRint.INTdis](#) can mask interrupts, including masking them acting as WFE wake-up events. For more information, see [DBGDSCRext, Debug Status and Control Register, External View on page G4-4126](#) and [DBGDSCRint, Debug Status and Control Register, Internal View on page G4-4130](#).

As shown in the list of wake-up events, an implementation can include IMPLEMENTATION DEFINED hardware mechanisms to generate wake-up events.

### ———— Note —————

For more information about [CPSR](#) masking see [Asynchronous exception masking controls on page G1-3468](#). If the configuration of the masking controls provided by EL2 and EL3 mean that a [CPSR](#) mask bit cannot mask the corresponding exception, then the physical exception is a WFE wake-up event, regardless of the value of the [CPSR](#) mask bit.

## The Event Register

The Event Register is a single bit register for each PE. When set, an event register indicates that an event has occurred, since the register was last cleared, that might require some action by the PE. Therefore, the PE must not suspend operation on issuing a WFE instruction.

The reset value of the Event Register is UNKNOWN.

The Event Register is set by:

- An SEV instruction.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

- A debug event that causes entry into Debug state.
- An exception return.

As shown in this list, the Event Register might be set by IMPLEMENTATION DEFINED mechanisms.

The Event Register is cleared only by a Wait For Event instruction.

Software cannot read or write the value of the Event Register directly.

### The Send Event instruction

The Send Event instruction, SEV, causes an event to be signaled to all PEs in the system. The mechanism that signals the event to the PEs is IMPLEMENTATION DEFINED. Hardware does not guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the SEV instruction. Therefore, ARM recommends that software includes a DSB instruction before an SEV instruction.

#### ———— Note ————

A DSB instruction ensures that no instruction, including any SEV instruction, that appears in program order after the DSB instruction, can execute until the DSB instruction has completed. For more information, see [Data Synchronization Barrier \(DSB\) on page E2-2354](#).

Execution of the Send Event instruction sets the Event Register.

The Send Event instruction is available at all privilege levels, see [SEV on page F7-2804](#).

### The Wait For Event instruction

The action of the Wait For Event instruction depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and completes immediately. Normally, if this happens the software makes another attempt to claim the lock.
- If the Event Register is clear the PE can suspend execution, and hardware might enter a low-power state. The PE can remain suspended until a WFE wake-up event or a reset occurs. When a WFE wake-up event occurs, or earlier if the implementation chooses, the WFE instruction completes.

The Wait For Event instruction, WFE, is available at all privilege levels, see [WFE on page F7-3022](#).

Software using the Wait For Event mechanism must tolerate spurious wake-up events, including multiple wake ups.

EL2 provides a bit that traps to EL2 any attempt to enter a low-power state from a Non-secure EL1 or EL0 mode. For more information see [Trapping use of the WFI and WFE instructions on page G1-3511](#).

### Pseudocode details of the Wait For Event lock mechanism

This section defines pseudocode functions that describe the operation of the Wait For Event mechanism.

The ClearEventRegister() pseudocode procedure clears the Event Register of the current PE.

The EventRegistered() pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear:

```
boolean EventRegistered();
```

The WaitForEvent() pseudocode procedure optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes a ClearEventRegister() to occur.

The SendEvent() pseudocode procedure sets the Event Register of every PE in the system.

## G1.11.10 Wait For Interrupt

AArch32 state supports Wait For Interrupt through an instruction, WFI, that is provided in the A32 and T32 instruction sets. For more information, see [WFI on page F7-3024](#).

When a PE issues a WFI instruction, its execution can be suspended, and a low-power state can be entered.

EL2 provides a bit that traps to EL2 any attempt to enter a low-power state from a Non-secure EL1 or EL0 mode. For more information see [Trapping use of the WFI and WFE instructions on page G1-3511](#).

The PE can remain suspended in its WFI state until it is reset, or one of the following *WFI wake-up events* occurs:

- A physical IRQ interrupt, regardless of the value of the [CPSR.I](#) bit.
- A physical FIQ interrupt, regardless of the value of the [CPSR.F](#) bit.
- A physical asynchronous abort, regardless of the value of the [CPSR.A](#) bit.
- In Non-secure state in any mode other than Hyp mode:
  - When [HCR.IMO](#) is set to 1, a virtual IRQ interrupt, regardless of the value of the [CPSR.I](#) bit.
  - When [HCR.FMO](#) is set to 1, a virtual FIQ interrupt, regardless of the value of the [CPSR.F](#) bit.
  - When [HCR.AMO](#) is set to 1, a virtual asynchronous abort, regardless of the value of the [CPSR.A](#) bit.
- An asynchronous debug event, when invasive debug is enabled and the debug event is permitted.

An implementation can include other IMPLEMENTATION DEFINED hardware mechanisms to generate WFI wake-up events.

When a WFI wake-up event is detected, or earlier if the implementation chooses, the WFI instruction completes.

WFI wake-up events cannot be masked by the mask bits in the [CPSR](#).

The architecture does not define the exact nature of the low power state, but the execution of a WFI instruction must not cause a loss of memory coherency.

### ———— Note —————

- Because debug events are WFI wake-up events, ARM strongly recommends that Wait For Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures the intervention of debug while waiting does not significantly change the function of the program being debugged.
- In some previous implementations of Wait For Interrupt, the idle loop is followed by exit functions that must be executed before taking the interrupt. The operation of Wait For Interrupt remains consistent with this model, and therefore differs from the operation of Wait For Event.
- Some implementations of Wait For Interrupt drain down any pending memory activity before suspending execution. The ARM architecture does not require this operation, and software must not rely on Wait For Interrupt operating in this way.

## Using WFI to indicate an idle state on bus interfaces

A common implementation practice is to complete any entry into powerdown routines with a WFI instruction. Typically, the WFI instruction:

1. Forces the completion of execution of any instructions that are in progress, and of all associated bus activity.
2. Suspends the execution of instructions by the PE.

The control logic required to do this tracks the activity of the bus interfaces used by the PE. This means it can signal to an external power controller when there is no ongoing bus activity.

However, memory-mapped and external debug interface accesses to debug registers must continue to be processed while the PE is in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

When the value of [DBGOSDLR.DLK](#), the OS Double Lock status bit, is set to 1, this idle state must not be signaled to the PE unless the system can guarantee, also, that the debug interface is idle.

---

**Note**

When separate core and debug power domains are implemented, the debug interface referred to in this section is the interface between the core and debug power domains, since the signal to the power controller indicates that the core power domain is idle. For more information about the power domains see [Power domains and debug on page H6-4425](#).

---

The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

### **Pseudocode details of Wait For Interrupt**

The `WaitForInterrupt()` pseudocode procedure optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.

## G1.12 Asynchronous exception behavior for exceptions taken from AArch32 state

In an implementation that does not include EL2 or EL3, the asynchronous exceptions behave as follows when EL1 and EL0 are both using AArch32:

- An asynchronous abort is taken to Abort mode.
- An IRQ exception is taken to IRQ mode.
- An FIQ exception is taken to FIQ mode.

These are the *default PE modes* for taking these exceptions.

However, the `CPSR.{A, I, F}` bits *mask* the asynchronous exceptions, meaning that when the value of one of these `CPSR` bits is 1, the corresponding exception is not taken.

If a masked asynchronous exceptions remains signalled, then the exception remains pending unless the value of the `CPSR` bit is changed to 0.

EL2 and EL3 provide controls that affect:

- The routing of these exceptions, see [Asynchronous exception routing controls on page G1-3467](#)
- Masking of these exceptions in Non-secure state, see [Asynchronous exception masking controls on page G1-3468](#).

Similar register control bits are provided regardless of whether EL2 and EL3 are using AArch32 or AArch64:

- The EL2 controls are provided by the `HCR` when EL2 is using AArch32, and by the `HCR_EL2` when EL2 is using AArch64.
- The EL3 controls are provided by the `SCR` when EL3 is using AArch32, and by the `SCR_EL3` when EL3 is using AArch64.

Therefore, most references to the `HCR` or `SCR` in this section are to entries in [Table J-1 on page AppxJ-5088](#), that disambiguates between AArch32 registers and AArch64 registers. However, the Execution states used by EL2 and EL3 do affect some aspects of the routing and masking of the asynchronous exceptions, see [Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-3470](#).

### G1.12.1 Virtual exceptions when an implementation includes EL2

When implemented, EL2 provides the following virtual exceptions, that correspond to the physical asynchronous exceptions:

- Virtual Abort, that corresponds to a physical external asynchronous abort.
- Virtual IRQ, that corresponds to a physical IRQ.
- Virtual FIQ, that corresponds to a physical FIQ.

When the value of the corresponding `HCR.{AMO, IMO, FMO}` bit is 1, a virtual exception is generated either:

- By setting a virtual interrupt pending bit, `HCR.{VA, VI, VF}`, to 1.
- For a Virtual IRQ or Virtual FIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller, for example from a Virtual GIC, as defined by the *ARM Generic Interrupt Controller Architecture Specification*.

In AArch32 state, a virtual exception is taken only from a Non-secure EL1 or EL0 mode. In any other mode, if the exception is generated it is not taken.

A virtual exception is taken in Non-secure state to the default mode for the corresponding physical exception. This means:

- A Virtual Abort is taken to Non-secure Abort mode.
- A Virtual IRQ is taken to Non-secure IRQ mode.
- A Virtual FIQ is taken to Non-secure FIQ mode.

Table G1-11 summarizes the HCR bits that route asynchronous exceptions to EL2, and the bits that generate the virtual exceptions.

**Table G1-11 HCR bits controlling asynchronous exceptions**

Exception	Routing the physical exception to EL2	Generating the virtual exception
Asynchronous abort	HCR.AMO	HCR.VA
IRQ	HCR.IMO	HCR.VI
FIQ	HCR.FMO	HCR.VF

The HCR.{VA, VI, VF} bits generate a virtual exception only if set to 1 when the value of the corresponding HCR.{AMO, IMO, FMO} is 1.

Similarly, if the implementation also includes EL3, the HCR.{AMO, IMO, FMO} bits route the corresponding physical exception to Hyp mode only if the physical exception is not routed to Monitor mode by the SCR.{EA, IRQ, FIQ} bit. For more information, see *Asynchronous exception routing controls on page G1-3467*.

When the value of an HCR.{AMO, IMO, FMO} control bit is 1, the corresponding mask bit in the CPSR:

- Does not mask the physical exception.
- Masks the virtual exception when the PE is executing in a Non-secure EL1 or EL0 mode.

Taking a Virtual Abort exception clears HCR.VA to zero. Taking a Virtual IRQ exception or a Virtual FIQ exception does not affect the value of HCR.VI or HCR.VF.

———— **Note** —————

This means that the exception handler for a Virtual IRQ exception or a Virtual FIQ exception must cause software that is executing at EL2 or EL3 to update the HCR to clear the appropriate virtual exception bit to 0.

See *WFE wake-up events on page G1-3461* and *Wait For Interrupt on page G1-3463* for information about how virtual exceptions affect wake up from power-saving states.

———— **Note** —————

A hypervisor can use virtual exceptions to signal exceptions to the current Guest OS. The Guest OS takes a virtual exception exactly as it would take the corresponding physical exception, and is unaware of any distinction between virtual exception and the corresponding physical exception.

**Effects of the HCR.{AMO, IMO, FMO} bits**

As described in this section, the HCR.{AMO, IMO, FMO} bits are part of the mechanism for enabling the virtual exceptions. In addition, for exceptions generated in Non-secure state:

- As mentioned in this section, affect the routing of the exceptions. See *Asynchronous exception routing controls on page G1-3467*.
- Affect the masking of the exceptions. See *Asynchronous exception masking controls on page G1-3468*.

## G1.12.2 Asynchronous exception routing controls

---

### Note

---

This section describes the behavior when all exception levels are using AArch32. For the differences when this is not the case see [Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-3470](#)

---

In an implementation that includes EL3 the following bits in the **SCR** control the routing of asynchronous exceptions, and also the routing of synchronous external aborts:

**SCR.EA** When the value of this bit is 1, any external abort is taken to EL3.

---

### Note

---

- Although this section describes the asynchronous exception routing controls, **SCR.EA** controls the routing of both synchronous and asynchronous external aborts.
  - The other classes of abort cannot be routed to EL3. For more information about the classification of aborts, see [VMSAv8-32 memory aborts on page G3-3647](#).
- 

**SCR.FIQ** When the value of this bit is 1, any FIQ exception is taken to EL3.

**SCR.IRQ** When the value of this bit is 1, any IRQ exception is taken to EL3.

When EL3 is using AArch32 and the value of one of the **SCR**.{EA, FIQ, IRQ} bits is 1, the exception is taken to Monitor mode.

Only Secure software can change the values of these bits.

In an implementation that includes EL2, the following bits in the **HCR** route asynchronous exceptions to EL2, for exceptions that are both:

- Taken from a Non-secure EL1 or EL0 mode.
- If the implementation also includes EL3, not configured, by the **SCR**.{EA, FIQ, IRQ} controls, to be taken to EL3.

**HCR.AMO** When the value of this bit is 1, an asynchronous external abort taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure Abort mode. If the implementation also includes EL3, this control applies only if the value of **SCR.EA** is 0. When the value of **SCR.EA** is 1, the value of the AMO bit is ignored.

---

### Note

---

[Figure G1-8 on page G1-3447](#) also shows how synchronous external aborts are handled.

---

**HCR.FMO** When the value of this bit is 1, an FIQ exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure FIQ mode. If the implementation also includes EL3, this control applies only if the value of **SCR.FIQ** is 0. When the value of **SCR.FIQ** is 1, the value of the FMO bit is ignored.

**HCR.IMO** When the value of this bit is 1, an IRQ exceptions taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure IRQ mode. If the implementation also includes EL3, this control applies only if the value of **SCR.IRQ** is 0. When the value of **SCR.IRQ** is 1, the value of the IMO bit is ignored.

When EL2 is using AArch32 and the value of one of the **HCR**.{AMO, FMO, IMO} bits is 1, the exception is taken to Hyp mode.

Only software executing in Hyp mode, or Secure software executing at EL3 with **SCR.NS** set to 1, can change the values of these bits. If EL3 is using AArch32, this requires the Secure software to be executing in Monitor mode.

The **HCR**.{AMO, FMO, IMO} bits also affect the masking of asynchronous exceptions in Non-secure state, as described in [Asynchronous exception masking controls on page G1-3468](#).

The **SCR**.{EA, FIQ, IRQ} and **HCR**.{AMO, FMO, IMO} bits have no effect on the routing of Virtual Abort, Virtual FIQ, and Virtual IRQ exceptions.

———— **Note** —————

When the PE is in Hyp mode:

- Physical asynchronous exceptions that are not routed to Monitor mode are taken to Hyp mode.
- Virtual exceptions are not signaled to the PE.

See also *Asynchronous exception behavior for exceptions taken from AArch32 state* on page G1-3465.

### G1.12.3 Asynchronous exception masking controls

———— **Note** —————

This section describes the behavior when all exception levels are using AArch32. For the differences when this is not the case see *Asynchronous exception routing and masking with higher Exception levels using AArch64* on page G1-3470

The **CPSR**.{A, I, F} bits can mask the taking of the corresponding exceptions from AArch32 state, as follows:

- **CPSR.A** can mask asynchronous aborts.
- **CPSR.I** can mask IRQ exceptions.
- **CPSR.F** can mask FIQ exceptions.

In an implementation that does not include either of EL2 and EL3, setting one of these bits to 1 masks the corresponding exception, meaning the exception cannot be taken.

In an implementation that includes EL2, the **HCR**.{AMO, IMO, FMO} bits modify the masking of exceptions taken from Non-secure state.

Similarly, in an implementation that includes EL3, the **SCR**.{AW, FW} bits modify the masking of exceptions taken from Non-secure state by the **CPSR**.{A, F} bits.

An implementation that includes only EL1 and EL0 does not provide any masking of the **CPSR**.{A, I, F} bits. The following subsections describe the masking of these bits in other implementations:

- *Asynchronous exception masking in an implementation that includes EL2 but not EL3.*
- *Asynchronous exception masking in an implementation that includes EL3 but not EL2.*
- *Asynchronous exception masking in an implementation that includes both EL2 and EL3 on page G1-3469.*
- *Summary of the asynchronous exception masking controls on page G1-3469.*

#### Asynchronous exception masking in an implementation that includes EL2 but not EL3

The **HCR**.{AMO, IMO, FMO} bits modify the effect of the **CPSR**.{A, I, F} bits. When the value of an **HCR**.{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding **CPSR**.{A, I, F} bit is ignored when the exception is taken from a Non-secure mode other than Hyp mode.

#### Asynchronous exception masking in an implementation that includes EL3 but not EL2

The **SCR**.{AW, FW} bits modify the effect of the **CPSR**.{A, F} bits. When the value of one of the **SCR**.{AW, FW} bits is 0, the corresponding **CPSR** bit is ignored when both of the follow apply:

- The corresponding exception is taken from Non-secure state.
- The value of the corresponding **SCR**.{EA, FIQ} bit is 1, routing the exception to EL3. This means the exception is routed to Monitor mode if EL3 is using AArch32.

———— **Note** —————

Whenever the value of **CPSR.I** is 1, IRQ exceptions are masked and cannot be taken.

### Asynchronous exception masking in an implementation that includes both EL2 and EL3

When the value of an **HCR**.{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding **CPSR**.{A, I, F} bit is ignored when both of the following apply:

- The exception is taken from Non-secure state.
- Either:
  - The corresponding **SCR**.{EA, IRQ, FIQ} bit routes the exception to Monitor mode.
  - The exception is taken from a Non-secure mode other than Hyp mode.

In addition, when the value of an **SCR**.{AW, FW} bit is 0, the value of the corresponding **CPSR**.{A, F} bit is ignored when all of the following apply:

- The exception is taken from Non-secure state.
- The corresponding **SCR**.{EA, FIQ} bit routes the exception to Monitor mode.
- The corresponding **HCR**.{AMO, FMO} mask override bit is set to 0.

### Summary of the asynchronous exception masking controls

The tables in this section show the masking controls for each of the **CPSR**.{A, I, F} bits. For an implementation that does not include all of the exception levels:

#### If the implementation includes only EL1 and EL0

The **CPSR** bits cannot be masked. The behavior is as shown in the *Secure* row of the tables.

#### If the implementation includes EL2 but not EL3

The behavior is as shown in the *Non-secure* table rows when the control bits in the **SCR** are both 0.

#### If the implementation includes EL3 but not EL2

The behavior is as shown in the table rows where the control bit in the **HCR** is 0.

Table G1-12 shows the controls of the masking of asynchronous exceptions by **CPSR**.A.

**Table G1-12 Control of masking by **CPSR**.A**

Security state	HCR.AMO	SCR.EA	SCR.AW	Mode	CPSR.A
Secure	x	x	x	x	Masks asynchronous aborts, when set to 1
Non-secure	0	0	x	x	Masks asynchronous aborts, when set to 1
			1	0	x
		1	1	x	Masks asynchronous aborts, when set to 1
	1	x	x	Not Hyp	Ignored
			0	x	Hyp
		1	x	x	Ignored

Table G1-13 shows the controls of the masking of FIQ exceptions by CPSR.F:

Table G1-13 Control of masking by CPSR.I

Security state	HCR.IMO	SCR.IRQ	Mode	CPSR.I
Secure	x	x	x	Masks IRQs, when set to 1
Non-secure	0	x	x	Masks IRQs, when set to 1
		1	Not Hyp	Ignored
	1	0	Hyp	Masks IRQs, when set to 1
		1	x	Ignored

Table G1-14 shows the controls of the masking of FIQ exceptions by CPSR.F:

Table G1-14 Control of masking by CPSR.F

Security state	HCR.FMO	SCR.FIQ	SCR.FW	Mode	CPSR.F	
Secure	x	x	x	x	Masks FIQs, when set to 1	
Non-secure	0	0	x	x	Masks FIQs, when set to 1	
			1	0	x	Ignored
		1	x	x	Not Hyp	Ignored
	1	0	x	x	Hyp	Masks FIQs, when set to 1
			1	x	x	Ignored
		1	1	x	x	Ignored

#### G1.12.4 Asynchronous exception routing and masking with higher Exception levels using AArch64

[Asynchronous exception routing controls](#) on page G1-3467 and [Asynchronous exception masking controls](#) on page G1-3468 give full descriptions of the routing and masking of the asynchronous exceptions when all Exception levels are using AArch32. However, when EL0 and EL1 are using AArch32:

- As already described, the SCR and HCR controls might be from Exception levels that are using AArch64.
- If EL3 is using AArch64, or EL2 is using AArch64, there are some changes to the asynchronous exception behaviors.

Therefore, the following sections summarize the asynchronous exception behaviors, taking account of the Execution state being used at EL2 and EL3:

- [Summary of physical interrupt routing](#).
- [Summary of physical interrupt masking](#) on page G1-3472.

#### Summary of physical interrupt routing

The following tables show the routing of physical interrupts. [Table G1-15 on page G1-3471](#) shows the routing of physical FIQ interrupts, [Table G1-16 on page G1-3471](#) shows the routing of physical IRQ interrupts, and [Table G1-17 on page G1-3472](#) shows the routing of physical asynchronous aborts.

In these tables, for exceptions that must be taken to an Exception level that is using AArch32, the table shows the target Exception level and PE mode. In these entries, *Mon* indicates Monitor mode, and *Abt* indicates Abort mode.

Table G1-15 Routing of physical FIQ exceptions

EL3 Execution state	Control bits			Target when take from:					
	SCR	HCR		Non-secure			Secure		
		FIQ	RW <sup>a</sup>	FMO <sup>b</sup>	EL0	EL1	EL2	EL0	EL1 <sup>c</sup>
AArch32	0	x	0	EL1 FIQ	EL1 FIQ	EL2 Hyp	EL3 FIQ	-	EL3 FIQ
			1	EL2 Hyp	EL2 Hyp	EL2 Hyp	EL3 FIQ	-	EL3 FIQ
	1	x	x	EL3 Mon	EL3 Mon	EL3 Mon	EL3 Mon	-	EL3 Mon
AArch64	0	0	0	EL1 FIQ	EL1 FIQ	EL2 Hyp	EL1 FIQ	EL1 FIQ	P <sup>d</sup>
		x	1	EL2 <sup>e</sup>	EL2 <sup>e</sup>	EL2 <sup>e</sup>	EL1 <sup>f</sup>	EL1 <sup>f</sup>	P <sup>d</sup>
		1	0	EL1	EL1	P <sup>d</sup>	EL1	EL1	P <sup>d</sup>
	1	x	x	EL3	EL3	EL3	EL3	EL3	EL3

- a. [SCR\\_EL3.RW](#). When 1, the next lower Exception level is using AArch64. This control is not present when EL3 is using AArch32.
- b. When the value of [HCR.TGE](#) is 1, the effective value of this bit is 1.
- c. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.
- d. Interrupt is not taken, but remains pending.
- e. If EL2 is using AArch32, taken to Hyp mode.
- f. If EL1 is using AArch32, taken to Abort mode.

Table G1-16 Routing of physical IRQ exceptions

EL3 Execution state	Control bits			Target when take from:					
	SCR	HCR		Non-secure			Secure		
		IRQ	RW <sup>a</sup>	IMO <sup>b</sup>	EL0	EL1	EL2	EL0	EL1 <sup>c</sup>
AArch32	0	x	0	EL1 IRQ	EL1 IRQ	EL2 Hyp	EL3 IRQ	-	EL3 IRQ
			1	EL2 Hyp	EL2 Hyp	EL2 Hyp	EL3 IRQ	-	EL3 IRQ
	1	x	x	EL3 Mon	EL3 Mon	EL3 Mon	EL3 Mon	-	EL3 Mon
AArch64	0	0	0	EL1 IRQ	EL1 IRQ	EL2 Hyp	EL1 IRQ	EL1 IRQ	P <sup>d</sup>
		x	1	EL2 <sup>e</sup>	EL2 <sup>e</sup>	EL2 <sup>e</sup>	EL1 <sup>f</sup>	EL1 <sup>f</sup>	P <sup>d</sup>
		1	0	EL1	EL1	P <sup>d</sup>	EL1	EL1	P <sup>d</sup>
	1	x	x	EL3	EL3	EL3	EL3	EL3	EL3

- a. [SCR\\_EL3.RW](#). When 1, the next lower Exception level is using AArch64. This control is not present when EL3 is using AArch32.
- b. When the value of [HCR.TGE](#) is 1, the effective value of this bit is 1.
- c. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.
- d. Interrupt is not taken, but remains pending.
- e. If EL2 is using AArch32, taken to Hyp mode.
- f. If EL1 is using AArch32, taken to Abort mode.

Table G1-17 Routing of physical Asynchronous aborts

EL3 Execution state	Control bits			Target when take from:					
	SCR	HCR		Non-secure			Secure		
		EA	RW <sup>a</sup>	AMO <sup>b</sup>	EL0	EL1	EL2	EL0	EL1 <sup>c</sup>
AArch32	0	x	0	EL1 Abt	EL1 Abt	EL2 Hyp	EL3 Abt	-	EL3 Abt
			1	EL2 Hyp	EL2 Hyp	EL2 Hyp	EL3 Abt	-	EL3 Abt
AArch64	0	0	x	EL3 Mon	EL3 Mon	EL3 Mon	EL3 Mon	-	EL3 Mon
			1	EL3 Mon	EL3 Mon	EL3 Mon	EL3 Mon	-	EL3 Mon
	1	x	0	EL1 Abt	EL1 Abt	EL2 Hyp	EL1 Abt	EL1Abt	P <sup>d</sup>
			1	EL2 <sup>e</sup>	EL2 <sup>e</sup>	EL2 <sup>e</sup>	EL1 <sup>f</sup>	EL1 <sup>f</sup>	P <sup>d</sup>
1	x	x	0	EL1	EL1	P <sup>d</sup>	EL1	EL1	P <sup>d</sup>
			1	EL3	EL3	EL3	EL3	EL3	EL3

- a. SCR\_EL3.RW. When 1, the next lower Exception level is using AArch64. This control is not present when EL3 is using AArch32.
- b. When the value of HCR.TGE is 1, the effective value of this bit is 1.
- c. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.
- d. Interrupt is not taken, but remains pending.
- e. If EL2 is using AArch32, taken to Hyp mode.
- f. If EL1 is using AArch32, taken to Abort mode.

### Summary of physical interrupt masking

The following tables show the masking of physical interrupts. Table G1-18 shows the masking of physical FIQ interrupts, Table G1-19 on page G1-3473 shows the masking of physical IRQ interrupts, and Table G1-20 on page G1-3474 shows the masking of physical asynchronous aborts. In these tables:

- M** Indicates that the exception is masked when the value of the CPSR mask bit is 1.
- T** Indicates that the exception is taken, regardless of the value of the CPSR mask bit.
- P** Indicates that the exception is not taken but remains pending. The value of the CPSR mask bit has no effect on this behavior.

Table G1-18 Masking of physical FIQ exceptions

EL3 Execution state	Control bits			Effect of CPSR.F <sup>a</sup> mask in Exception level						
	SCR	HCR		Non-secure			Secure			
		FIQ	FW	RW <sup>b</sup>	FMO <sup>c</sup>	EL0	EL1	EL2	EL0	EL1 <sup>d</sup>
AArch32	0	x	x	0	M	M	M	M	-	M
			1	T	T	M	M	-	M	
AArch64	0	0	x	0	T	T	T	M	-	M
			1	M	M	M	M	-	M	
	1	x	x	1	T	T	T	M	-	M
			1	T	T	T	M	-	M	

Table G1-18 Masking of physical FIQ exceptions (continued)

EL3 Execution state	Control bits			Effect of CPSR.F <sup>a</sup> mask in Exception level							
	SCR			HCR	Non-secure			Secure			
		FIQ	FW		RW <sup>b</sup>	FMO <sup>c</sup>	EL0	EL1	EL2	EL0	EL1 <sup>d</sup>
AArch64	0	x	0	0	M	M	M	M	M	P	
				1	T	T	M	M	M	P	
				1	0	M	M	P	M	M	P
					1	T	T	M	M	M	P
1	x	x	x	T	T	T	T	T	M		

- a. Or the PSTATE.F mask in an Exception level that is using AArch64.
- b. SCR\_EL3 only, this control is not present when EL3 is using AArch32. When the value of RW is 1, the next lower Exception level is using AArch64.
- c. When the value of HCR.TGE is 1, the effective value of this bit is 1.
- d. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.

Table G1-19 Masking of physical IRQ exceptions

EL3 Execution state	Control bits			Effect of CPSR.I <sup>a</sup> mask in Exception level							
	SCR			HCR	Non-secure			Secure			
		IRQ	RW <sup>b</sup>		IMO <sup>c</sup>	EL0	EL1	EL2	EL0	EL1 <sup>d</sup>	EL3
AArch32	0	x	0	0	M	M	M	M	-	M	
				1	T	T	M	M	-	M	
				1	0	M	M	M	M	-	M
					1	T	T	T	M	-	M
AArch64	0	0	0	0	M	M	M	M	M	P	
				1	T	T	M	M	M	P	
				1	0	M	M	P	M	M	P
					1	T	T	M	M	M	P
1	x	x	x	T	T	T	T	T	M		

- a. Or the PSTATE.I mask in an Exception level that is using AArch64.
- b. SCR\_EL3 only, this control is not present when EL3 is using AArch32. When the value of RW is 1, the next lower Exception level is using AArch64.
- c. When the value of HCR.TGE is 1, the effective value of this bit is 1.
- d. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.

Table G1-20 Masking of physical Asynchronous aborts

EL3 Execution state	Control bits			Effect of CPSR.A <sup>a</sup> mask in Exception level							
	SCR EA	AW	RW <sup>b</sup>	HCR	Non-secure			Secure			
				AMO <sup>c</sup>	EL0	EL1	EL2	EL0	EL1 <sup>d</sup>	EL3	
AArch32	0	x	x	0	M	M	M	M	-	M	
				1	T	T	M	M	-	M	
	1	0	x	0	T	T	T	M	-	M	
		1	x	0	M	M	M	M	-	M	
AArch64	0	x	0	0	M	M	M	M	M	P	
				1	T	T	M	M	M	P	
				1	0	M	M	P	M	M	P
				1	T	T	M	M	M	P	
	1	x	x	x	T	T	T	T	T	M	

- Or the PSTATE.A mask in an Exception level that is using AArch64.
- SCR\_EL3 only, this control is not present when EL3 is using AArch32. When the value of RW is 1, the next lower Exception level is using AArch64.
- When the value of HCR.TGE is 1, the effective value of this bit is 1.
- When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.

## G1.13 AArch32 state exception descriptions

*Handling exceptions that are taken to an Exception level using AArch32 on page G1-3431* gives general information about exception handling. This section describes each of the exceptions, in the following subsections:

- *Reset.*
- *Undefined Instruction exception on page G1-3476.*
- *Hyp Trap exception on page G1-3478.*
- *Supervisor Call (SVC) exception on page G1-3479.*
- *Secure Monitor Call (SMC) exception on page G1-3480.*
- *Hypervisor Call (HVC) exception on page G1-3481.*
- *Prefetch Abort exception on page G1-3481.*
- *Data Abort exception on page G1-3483.*
- *Virtual Abort exception on page G1-3485.*
- *IRQ exception on page G1-3486.*
- *Virtual IRQ exception on page G1-3488.*
- *FIQ exception on page G1-3489.*
- *Virtual FIQ exception on page G1-3490.*

*Additional pseudocode functions for exception handling on page G1-3491* gives additional pseudocode that is used in the pseudocode descriptions of a number of the exceptions.

### G1.13.1 Reset

On an ARM PE, when the Reset input is asserted the PE stops execution. When Reset is deasserted, the PE then starts executing instructions in the highest implemented Exception level. If that Exception level is using AArch32, then it starts execution:

- In Secure state, if the implementation includes EL3.
- With interrupts disabled:
  - In Hyp mode, if the highest implemented Exception level is EL2.
  - In Supervisor mode, otherwise.

Reset returns some PE state to architecturally-defined or IMPLEMENTATION DEFINED values, and makes other state UNKNOWN. For more information see:

- *Behavior of caches at reset on page G2-3526.*
- *Enabling stages of address translation on page G3-3572.*
- *TLB behavior at reset on page G3-3631.*
- *Reset behavior of CP14 and CP15 registers on page G3-3695.*

When reset is deasserted, execution starts either:

- From an IMPLEMENTATION DEFINED address.  
Software might be able to identify this address:
  - If reset is into EL3, by reading the reset value of **MVBAR**. That is, after coming out of reset, by reading **MVBAR** before the boot software has updated it.
  - If reset is into EL2 or EL1, by reading **RVBAR**.

It is IMPLEMENTATION DEFINED whether this discovery mechanism is supported. **RVBAR** can only be implemented at the highest implemented Exception level, and only if that Exception level is not EL3. If **RVBAR** is not implemented, and at all Exception levels other than the highest implemented Exception level, the encoding for **RVBAR** is UNDEFINED.

- If reset is into EL3 or EL1, from the low or high reset vector address, `0x00000000` or `0xFFFF0000`, as determined by the reset value of the **SCTLR.V** bit. This reset value can be determined by an IMPLEMENTATION DEFINED configuration input signal.

When execution starts, system behavior depends on the reset value of the **CPSR**, as defined by the `TakeReset()` pseudocode function that is defined later in this section. See also [The Current Program Status Register \(CPSR\) on page G1-3422](#).

The ARM architecture does not define any way of returning to a previous execution state from a reset.

———— **Note** ————

- A Reset exception does not reset the value of all of the debug registers. For more information see [Reset and debug on page H8-4463](#).
- The ARM architecture does not distinguish between multiple levels of reset. A system can provide multiple distinct levels of reset that reset different parts of the system. These all correspond to this single reset exception.

## Pseudocode description of taking the Reset exception

The `TakeReset()` pseudocode procedure describes how the PE takes the exception:

```
// TakeReset()
// =====

TakeReset()
  // Enter Supervisor mode and (if relevant) Secure state, and reset CP15. This affects
  // the Banked versions and values of various registers accessed later in the code.
  // Also reset other system components.
  CPSR.M = '10011'; // Supervisor mode
  if HaveSecurityExt() then SCR.NS = '0';
  ResetControlRegisters();
  if HaveAdvSIMDorVFP() then FPEXC.EN = '0'; SUBARCHITECTURE_DEFINED further resetting;
  if HaveThumbEE() then TEECR.XED = '0';
  if HaveJazelle() then JMCR.JE = '0'; SUBARCHITECTURE_DEFINED further resetting;

  // Further CPSR changes: all interrupts disabled, IT state reset, instruction set
  // and endianness according to the SCTLR values produced by the above call to
  // ResetControlRegisters().
  CPSR.I = '1'; CPSR.F = '1'; CPSR.A = '1';
  CPSR.IT = '00000000';
  CPSR.J = '0'; CPSR.T = SCTLR.TE; // TE=0: ARM, TE=1: Thumb
  CPSR.E = SCTLR.EE; // EE=0: little-endian, EE=1: big-endian

  // All registers, bits and fields not reset by the above pseudocode or by the
  // BranchTo() call below are UNKNOWN bitstrings after reset. In particular, the
  // return information registers R14_svc and SPSR_svc have UNKNOWN values, so that
  // it is impossible to return from a reset in an architecturally defined way.

  // Branch to Reset vector.
  BranchTo(ExcVectorBase() + 0);
```

### G1.13.2 Undefined Instruction exception

An Undefined Instruction exception might be caused by:

- A coprocessor instruction that is not accessible because of the settings in one or more of the **CPACR**, **NSACR**, and the **HCPTR**.
- A coprocessor instruction that is not implemented.
- A coprocessor instruction that causes an exception during execution, for example a trapped floating-point exception on a floating-point instruction, see [Floating-point exceptions on page E1-2307](#).
- An instruction that is UNDEFINED.
- An attempt to execute an instruction in an unimplemented instruction set state, see [Exception return to an unimplemented instruction set state on page G1-3458](#).

- Division by zero in an SDIV or UDIV instruction.

By default, an Undefined Instruction exception is taken to Undefined mode, but an Undefined Instruction exception can be taken EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see [Determining the PE mode to which the Undefined Instruction exception is taken on page G1-3443](#).

The Undefined Instruction exception can provide:

- Signaling of an illegal instruction execution.
- *Lazy context switching* of coprocessor registers.

The preferred return address for an Undefined Instruction exception is the address of the instruction that generated the exception. This return is performed as follows:

- If returning from Secure or Non-secure Undefined mode, the exception return uses the **SPSR** and **LR\_und** values generated by the exception entry, as follows:
  - If **SPSR**.{J, T} are both 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
  - If **SPSR**.T is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.
- If returning from Hyp mode, the exception return is performed by an ERET instruction, using the **SPSR** and **ELR\_hyp** values generated by the exception entry.

For more information, see [Exception return to an Exception level using AArch32 on page G1-3454](#).

———— **Note** —————

If handling the Undefined Instruction exception requires instruction emulation, followed by return to the next instruction after the instruction that caused the exception, the instruction emulator must use the instruction length to calculate the correct return address, and to calculate the updated values of the IT bits if necessary.

### Pseudocode description of taking the Undefined Instruction exception

The TakeUndefInstrException() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeUndefInstrException()
// =====

AArch32.TakeUndefInstrException()
  assert !AArch32.GeneralExceptionsToAArch64();

  take_to_hyp = PSTATE.EL == EL2;
  route_to_hyp = AArch32.GeneralExceptionsToHyp();

  bits(32) preferred_exception_return = ThisInstrAddr();
  vect_offset = 0x4;
  lr_offset = if CurrentInstrSet() == InstrSet_A32 then 8 else 4;

  if take_to_hyp || route_to_hyp then
    exception = ExceptionSyndrome(Exception_Uncategorized);
    if take_to_hyp then
      AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
    else
      AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
  else
    AArch32.EnterMode(M32_Undef, preferred_exception_return, lr_offset, vect_offset);
```

[Additional pseudocode functions for exception handling on page G1-3491](#) defines the EnterHypMode() pseudocode procedure.

## Conditional execution of undefined instructions

The conditional execution rules described in [Conditional execution on page F2-2416](#) apply to all instructions. This includes undefined instructions and other instructions that would cause entry to the Undefined Instruction exception.

If such an instruction fails its condition check, the behavior depends on the architecture profile and the potential cause of entry to the Undefined Instruction exception, as follows:

- If the potential cause is the execution of the instruction itself and depends on data values used by the instruction, the instruction executes as a NOP and does not cause an Undefined Instruction exception.
- If the potential cause is the execution of an earlier coprocessor instruction, or the execution of the instruction itself without dependence on the data values used by the instruction, it is IMPLEMENTATION DEFINED whether the instruction executes as a NOP or causes an Undefined Instruction exception.

An implementation must handle all such cases in the same way.

### ———— Note —————

Before ARMv7, all implementations executed any instruction that failed its condition check as a NOP, even if it would otherwise have caused an Undefined Instruction exception. An Undefined Instruction handler written for these implementations might assume without checking that the undefined instruction passed its condition check. Such an Undefined Instruction handler is likely to need rewriting, to check the condition is passed, before it functions correctly on all AArch32 implementations.

## Interaction of UNPREDICTABLE and UNDEFINED instruction behavior

If this manual describes an instruction as both UNPREDICTABLE and UNDEFINED then the instruction is UNPREDICTABLE.

### ———— Note —————

An example of this is where both:

- An instruction, or instruction class, is made UNDEFINED by some general principle, or by a configuration field.
- A particular encoding of that instruction or instruction class is specified as UNPREDICTABLE.

### G1.13.3 Hyp Trap exception

The Hyp Trap exception is implemented only as part of EL2.

A Hyp Trap exception is generated if the PE is running in a Non-secure mode other than Hyp mode, and commits for execution an instruction that is trapped to Hyp mode. Instruction traps are enabled by setting bits to 1 in the [HCR](#), [HCPTR](#), [HDCR](#), or [HSTR](#). For more information see [AArch32 control of traps to the hypervisor on page G1-3503](#).

A Hyp Trap exception is taken to Hyp mode.

The preferred return address for a Hyp Trap exception is the address of the trapped instruction. The exception return is performed by an ERET instruction, using the [SPSR](#) and [ELR\\_hyp](#) values generated by the exception entry.

### ———— Note —————

The [SPSR](#) and [ELR\\_hyp](#) values generated on exception entry can be used, without modification, for an exception return to re-execute the trapped instruction. If the exception handler emulates the trapped instruction, and must return to the following instruction, the emulation of the instruction must include modifying [ELR\\_hyp](#), and possibly updating [SPSR\\_hyp](#).

For related information, see [General information about traps to the hypervisor on page G1-3504](#).

## Pseudocode description of taking the Hyp Trap exception

The TakeHypTrapException() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeHypTrapException()
// =====
// Exceptions routed to Hyp mode as a Hyp Trap exception.

AArch32.TakeHypTrapException(ExceptionRecord exception)
    assert HaveEL(EL2) && !IsSecure() && ELUsingAArch32(EL2);

    bits(32) preferred_exception_return = ThisInstrAddr();
    AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
```

*Additional pseudocode functions for exception handling on page G1-3491* defines the EnterHypMode() pseudocode procedure.

### G1.13.4 Supervisor Call (SVC) exception

The Supervisor Call instruction, SVC, requests a supervisor function, typically to request an operating system function. When EL1 is using AArch32, executing an SVC instruction causes the PE to enter Supervisor mode. For more information, see *SVC (previously SWI) on page F7-2926*.

#### ———— Note ————

In an implementation that includes EL2:

- When an SVC instruction is executed in Hyp mode, the Supervisor Call exception is taken to Hyp mode. For more information see *SVC (previously SWI) on page F7-2926*.
- When the HCR.TGE bit is set to 1, the Supervisor Call exception generated by execution of an SVC instruction in Non-secure User mode is routed to Hyp mode. For more information, see *Supervisor Call exception, when HCR.TGE is set to 1 on page G1-3452*.

By default, a Supervisor Call exception is taken to Supervisor mode, but a Supervisor Call exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see *Determining the PE mode to which the Supervisor Call exception is taken on page G1-3444*.

The preferred return address for a Supervisor Call exception is the address of the next instruction after the SVC instruction. This return is performed as follows:

- If returning from Secure or Non-secure Supervisor mode, the exception return uses the SPSR and LR\_svc values generated by the exception entry, in an exception return instruction without subtraction.
- If returning from Hyp mode, the exception return is performed by an ERET instruction, using the SPSR and ELR\_hyp values generated by the exception entry.

For more information, see *Exception return to an Exception level using AArch32 on page G1-3454*.

## Pseudocode description of taking the Supervisor Call exception

The TakeSVCEXception() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeSVCEXception()
// =====

AArch32.TakeSVCEXception(bits(16) immediate)
    assert !AArch32.GeneralExceptionsToAArch64();

    AArch32.ITAdvance();
    SSAdvance();

    take_to_hyp = PSTATE.EL == EL2;
    route_to_hyp = AArch32.GeneralExceptionsToHyp();
```

```
bits(32) preferred_exception_return = NextInstrAddr();  
vect_offset = 0x08;  
lr_offset = 0;  
  
if take_to_hyp || route_to_hyp then  
    exception = ExceptionSyndrome(Exception_SupervisorCall);  
    exception.syndrome<15:0> = immediate;  
    if take_to_hyp then  
        AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);  
    else  
        AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);  
else  
    AArch32.EnterMode(M32_Svc, preferred_exception_return, lr_offset, vect_offset);
```

*Additional pseudocode functions for exception handling on page G1-3491* defines the EnterHypMode() pseudocode procedure.

### G1.13.5 Secure Monitor Call (SMC) exception

The Secure Monitor Call exception is implemented only as part of EL3. When EL3 is using AArch32, the exception is taken to Monitor mode.

The Secure Monitor Call instruction, SMC, requests a Secure Monitor function. When EL3 is using AArch32, executing an SMC instruction causes the PE to enter Monitor mode. For more information, see *SMC (previously SMI) on page F7-3058*.

#### ———— Note —————

In an implementation that includes EL2, execution of an SMC instruction in a Non-secure EL1 mode can be trapped to EL2. When EL2 is using AArch32, this means that when the value of the HCR.TSC bit is 1, execution of an SMC instruction in a Non-secure EL1 mode generates a Hyp Trap Exception that is taken to Hyp mode. For more information see *Trapping use of the SMC instruction on page G1-3510*.

The preferred return address for a Secure Monitor Call exception is the address of the next instruction after the SMC instruction. This return is performed using the SPSR and LR\_mon values generated by the exception entry, using an exception return instruction without a subtraction.

For more information, see *Exception return to an Exception level using AArch32 on page G1-3454*.

#### ———— Note —————

The exception handler can return to the SMC instruction itself by returning using a subtraction of 4, without any adjustment to the SPSR.IT[7:0] bits. If it does this, the return occurs, then interrupts or external aborts might occur and be handled, then the SMC instruction is re-executed and another Secure Monitor Call exception occurs.

This relies on:

- The SMC instruction being used correctly, either outside an IT block or as the last instruction in an IT block, so that the SPSR.IT[7:0] bits indicate unconditional execution.
- The Secure Monitor Call handler not changing the result of the original conditional execution test for the SMC instruction.

### Pseudocode description of taking the Secure Monitor Call exception

The TakeSMCException() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeSMCException()  
// =====  
  
AArch32.TakeSMCException()  
    assert HaveEL(EL3) && ELUsingAArch32(EL3);  
  
    AArch32.ITAdvance();
```

```

SSAdvance();

bits(32) preferred_exception_return = NextInstrAddr();
vect_offset = 0x08;
lr_offset = 0;

AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);

```

*Additional pseudocode functions for exception handling on page G1-3491* defines the EnterMonitorMode() pseudocode procedure.

### G1.13.6 Hypervisor Call (HVC) exception

The Hypervisor Call exception is implemented only as part of EL2.

The Hypervisor Call instruction, HVC, requests a hypervisor function. When EL2 is using AArch32, executing an HVC instruction generates a Hypervisor Call exception that is taken to Hyp mode. For more information, see [HVC on page F7-3040](#).

The preferred return address for a Hypervisor Call exception is the address of the next instruction after the HVC instruction. The exception return is performed by an ERET instruction, using the SPSR and ELR\_hyp values generated by the exception entry.

For more information, see [Exception return to an Exception level using AArch32 on page G1-3454](#).

When EL2 is using AArch32, executing an HVC instruction transfers the immediate argument of the instruction to the HSR. The exception handler retrieves the argument from the HSR, and therefore does not have to access the original HVC instruction. For more information see [Use of the HSR on page G3-3672](#).

#### Pseudocode description of taking the Hypervisor Call exception

The TakeHVCEXception() pseudocode procedure describes how the PE takes the exception:

```

// AArch32.TakeHVCEXception()
// =====

AArch32.TakeHVCEXception(bits(16) immediate)
  assert ELUsingAArch32(EL2);

  AArch32.ITAdvance();
  SSAdvance();

  exception = ExceptionSyndrome(Exception_HypervisorCall);
  exception.syndrome<15:0> = immediate;
  bits(32) preferred_exception_return = NextInstrAddr();
  vect_offset = 0x08;

  if PSTATE.EL == EL2 then
    AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
  else
    AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);

```

*Additional pseudocode functions for exception handling on page G1-3491* defines the EnterHypMode() pseudocode procedure.

### G1.13.7 Prefetch Abort exception

A Prefetch Abort exception can be generated by:

- A synchronous memory abort on an instruction fetch.

———— **Note** —————

Asynchronous aborts on instruction fetches are reported using the Data Abort exception, see [Data Abort exception on page G1-3483](#).

A Prefetch Abort exception entry is synchronous to the instruction whose fetch aborted.

For more information about memory aborts see [VMSAv8-32 memory aborts on page G3-3647](#).

- A Breakpoint, Vector catch or BKPT instruction debug event, see [Breakpoint debug events and Vector Catch exception on page H2-4333](#).

———— **Note** —————

If an implementation fetches instructions speculatively, it must handle a synchronous abort on such an instruction fetch by:

- Generating a Prefetch Abort exception only if the instruction would be executed in a simple sequential execution of the program.
- Ignoring the abort if the instruction would not be executed in a simple sequential execution of the program.

By default, when EL1 is using AArch32, a Prefetch Abort exception is taken to Abort mode, but a Prefetch Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information, see [Determining the PE mode to which the Prefetch Abort exception is taken on page G1-3446](#).

The preferred return address for a Prefetch Abort exception is the address of the aborted instruction. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the [SPSR](#) and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - SPSR\_abt and LR\_abt if returning from Abort mode.
  - SPSR\_mon and LR\_mon if returning from Monitor mode.
- If returning from Hyp mode, using the [SPSR\\_hyp](#) and [ELR\\_hyp](#) values generated by the exception entry, using an ERET instruction.

For more information, see [Exception return to an Exception level using AArch32 on page G1-3454](#).

## Pseudocode description of taking the Prefetch Abort exception

The TakePrefetchAbortException() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakePrefetchAbortException()
// =====

AArch32.TakePrefetchAbortException(bits(32) vaddress, FaultRecord fault)

    route_to_monitor = HaveEL(EL3) && SCR_GEN[.EA] == '1' && IsExternalAbort(fault);
    take_to_hyp = PSTATE.EL == EL2;
    route_to_hyp = (AArch32.GeneralExceptionsToHyp() || IsSecondStage(fault) ||
        (HaveEL(EL2) && !IsSecure() && IsDebugException(fault) && HDCR.TDE == '1'));

    bits(32) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0C;
    lr_offset = 4;

    secure = route_to_monitor || IsSecure();

    if IsDebugException(fault) then DBGDSCRext.MOE = fault.debugmoe;

    if route_to_monitor then
        AArch32.ReportPrefetchAbort(secure, fault, vaddress);
        AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);
    elsif take_to_hyp || route_to_hyp then
        if fault.type == Fault_Alignment then // PC Alignment fault
```

```

    exception = ExceptionSyndrome(Exception_PCAAlignment);
  else
    exception = AArch32.AbortSyndrome(Exception_InstructionAbort, fault, vaddress);
  if take_to_hyp then
    AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
  else
    AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
  else
    AArch32.ReportPrefetchAbort(secure, fault, vaddress);
    AArch32.EnterMode(M32_Abort, preferred_exception_return, lr_offset, vect_offset);

```

*Additional pseudocode functions for exception handling on page G1-3491* defines the `EnterMonitorMode()` and `EnterHypMode()` pseudocode procedures.

## G1.13.8 Data Abort exception

A Data Abort exception can be generated by:

- A synchronous abort on a data read or write memory access. Exception entry is synchronous to the instruction that generated the memory access.
- An asynchronous abort. The memory access that caused the abort can be any of:
  - A data read or write access.
  - An instruction fetch.
  - In a VMSA memory system, a translation table access.

Exception entry occurs asynchronously, and is similar to an interrupt.

As described in *Asynchronous exception masking controls on page G1-3468*, asynchronous aborts can be masked. When this happens, a generated asynchronous abort is not taken until it is not masked.

### ———— Note —————

There are no asynchronous internal aborts in the ARM architecture, so asynchronous aborts are always asynchronous external aborts.

- A Watchpoint debug event, see *Breakpoint and Watchpoint debug events on page H2-4330*.

### ———— Note —————

Data Abort exceptions generated by Watchpoint debug events can be either asynchronous or synchronous. However, the `CPSR.A` bit has no effect on the taking of such an exception, regardless of whether it is asynchronous.

By default, when EL1 is using AArch32 a Data Abort exception is taken to Abort mode, but a Data Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information see *Determining the PE mode to which the Data Abort exception is taken on page G1-3447*.

For more information about memory aborts see *VMSAv8-32 memory aborts on page G3-3647*.

The preferred return address for a Data Abort exception is the address of the instruction that generated the aborting memory access, or the address of the instruction following the instruction boundary at which an asynchronous Data Abort exception was taken. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the `SPSR` and `LR` values generated by the exception entry, using an exception return instruction with a subtraction of 8. This means using:
  - `SPSR_abt` and `LR_abt` if returning from Abort mode.
  - `SPSR_mon` and `LR_mon` if returning from Monitor mode.
- If returning from Hyp mode, using the `SPSR_hyp` and `ELR_hyp` values generated by the exception entry, using an `ERET` instruction.

For more information, see [Exception return to an Exception level using AArch32](#) on page G1-3454.

## Pseudocode description of taking the Data Abort exception

The TakeDataAbortException() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeDataAbortException()
// =====

AArch32.TakeDataAbortException(bits(32) vaddress, FaultRecord fault)

    route_to_monitor = HaveEL(EL3) && SCR_GEN[.EA == '1' && IsExternalAbort(fault)];
    take_to_hyp = PSTATE.EL == EL2;
    route_to_hyp = (AArch32.GeneralExceptionsToHyp() || IsSecondStage(fault) ||
        (HaveEL(EL2) && !IsSecure() && IsDebugException(fault) && HDCR.TDE == '1'));

    bits(32) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x10;
    lr_offset = 8;

    secure = route_to_monitor || IsSecure();

    if IsDebugException(fault) then DBGDSCRext.MOE = fault.debugmoe;

    if route_to_monitor then
        AArch32.ReportDataAbort(secure, fault, vaddress);
        AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);
    elseif take_to_hyp || route_to_hyp then
        exception = AArch32.AbortSyndrome(Exception_DataAbort, fault, vaddress);
        if take_to_hyp then
            AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
        else
            AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
    else
        AArch32.ReportDataAbort(secure, fault, vaddress);
        AArch32.EnterMode(M32_Abort, preferred_exception_return, lr_offset, vect_offset);
```

[Additional pseudocode functions for exception handling on page G1-3491](#) defines the EnterMonitorMode() and EnterHypMode() pseudocode procedures.

## Effects of data-aborted instructions

An instruction that accesses data memory can modify memory by storing one or more values. If the execution of such an instruction generates a Data Abort exception, or causes Debug state entry because of a watchpoint set on the instruction, the value of each memory location that the instruction stores to is:

- Unchanged for any location for which one of the following applies:
  - A stage of address translation fault is generated.
  - A Watchpoint is generated.
  - An external abort is generated, if that external abort is taken synchronously.
- UNKNOWN for any location for which no exception is generated.

If the access to a memory location generates an external abort that is taken asynchronously, it is outside the scope of the architecture to define the effect of the store on that memory location, because this depends on the system-specific nature of the external abort. However, in general, ARM recommends that such locations are unchanged.

For external aborts and Watchpoints, where in principle faulting could be identified at byte or halfword granularity, the size of a location in this definition is the size for which a memory access is single-copy atomic.

In AArch32 state, instructions that access data memory can modify registers in the following ways:

- By loading values into one or more of the general-purpose registers. The registers loaded can include the PC.
- By loading values into one or more of the registers in the Advanced SIMD and floating-point register bank.

- By specifying *base register writeback*, in which the base register used in the address calculation has a modified value written to it. All instructions that support base register writeback have UNPREDICTABLE results if base register writeback is specified with the PC as the base register. Only general-purpose registers can be modified reliably in this way.
- By a direct or indirect write to one or more coprocessor registers, for example:
  - An LDC instruction is a *direct write* to a coprocessor register with a value read from memory.
  - An STC instruction that reads `DBGDTRTXint` makes an *indirect write* to `DBGDSCRint.RXfull`.
- By modifying the `CPSR`.

If the execution of such an instruction generates a synchronous Data Abort exception, the following rules determine the values left in these registers:

- On entry to the Data Abort exception handler:
  - The PC value is the Data Abort vector address, see [Exception vectors and the exception base address on page G1-3431](#).
  - The `LR_abt` value is determined from the address of the aborted instruction.  
Neither value is affected by the results of any load specified by the instruction.
- The base register is restored to its original value if either:
  - The aborted instruction is a load and the list of registers to be loaded includes the base register.
  - The base register is being written back.
- If the instruction only loads one general-purpose register the value in that register is unchanged.
- If the instruction loads more than one general-purpose register, UNKNOWN values are left in destination registers other than the PC and the base register of the instruction.
- If the instruction affects any registers in the Advanced SIMD and floating-point register bank, UNKNOWN values are left in the registers that are affected.
- `CPSR` bits that are not defined as updated on exception entry retain their current value.
- If the instruction is a STREX, STREXB, STREXH, or STREXD, `<Rd>` is not updated.

After taking a Data Abort exception, the state of the exclusive monitors is UNKNOWN. Therefore, ARM strongly recommends that the abort handler performs a CLREX instruction, or a dummy STREX instruction, to clear the exclusive monitor state.

### The ARM abort model

The abort model used by an ARM PE is described as a *Base Restored Abort Model*. This means that if a synchronous Data Abort exception is generated by executing an instruction that specifies base register writeback, the value in the base register is unchanged.

The abort model applies uniformly across all instructions.

## G1.13.9 Virtual Abort exception

The Virtual Abort exception is implemented only as part of EL2.

A Virtual Abort exception is generated if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of `CPSR.A` is 0.
- Either:
  - EL2 is using AArch32 and the values of the `HCR.{AMO, VA}` bits are {1, 1}.
  - EL2 is using AArch64 and the values of the `HCR_EL2.{AMO, VA}` bits are {1, 1}.

The conditions for generating a Virtual Abort exception mean the exception is always:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure Abort mode.

For more information see [Virtual exceptions when an implementation includes EL2](#) on page G1-3465.

———— **Note** —————

Because the Virtual Abort exception is always taken to Non-secure Abort mode, on exception entry the preferred return address is always saved to LR\_abt.

The preferred return address for a Virtual Abort exception is the address of the instruction immediately after the instruction boundary where the exception was taken. This return is performed using the [SPSR](#) and LR\_abt values generated by the exception entry, using an exception return instruction without subtraction.

### Pseudocode description of taking the Virtual Asynchronous Abort exception

The TakeVirtualAsyncAbortException() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeVirtualAsyncAbortException()
// =====

AArch32.TakeVirtualAsyncAbortException()
    assert HaveEL(EL2) && !IsSecure() && PSTATE.EL != EL2 && HCR.TGE == '0';

    if !ELUsingAArch32(EL1) then
        AArch64.TakeVirtualSystemErrorException();

    secure = FALSE;
    parity = FALSE;
    extflag = bit IMPLEMENTATION_DEFINED "Virtual Asynchronous Abort Ext bit";
    fault = AArch32.AsyncExternalAbort(parity, extflag);
    vaddress = bits(32) UNKNOWN;

    vect_offset = 0x10;
    bits(32) preferred_exception_return = ThisInstrAddr();
    lr_offset = 8;

    HCR.VA = '0';
    AArch32.ReportDataAbort(secure, fault, vaddress);
    AArch32.EnterMode(M32_Abort, preferred_exception_return, lr_offset, vect_offset);
```

#### G1.13.10 IRQ exception

The IRQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an IRQ interrupt request input to the PE.

When an IRQ exception is taken, exception entry is precise to an instruction boundary.

As described in [Asynchronous exception masking controls](#) on page G1-3468, IRQ exceptions can be masked. When this happens, a generated IRQ exception is not taken until it is not masked.

By default, when EL1 is using AArch32, an IRQ exception is taken to IRQ mode, but an IRQ exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information, see [Determining the PE mode to which the physical IRQ exception is taken](#) on page G1-3448.

The preferred return address for an IRQ exception is the address of the instruction following the instruction boundary at which the exception was taken. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the [SPSR](#) and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - [SPSR\\_irq](#) and [LR\\_irq](#) if returning from IRQ mode.
  - [SPSR\\_mon](#) and [LR\\_mon](#) if returning from Monitor mode.
- If returning from Hyp mode, using the [SPSR\\_hyp](#) and [ELR\\_hyp](#) values generated by the exception entry, using an ERET instruction.

For more information, see [Exception return to an Exception level using AArch32](#) on page G1-3454.

## Pseudocode description of taking the IRQ exception

The TakePhysicalIRQException() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakePhysicalIRQException()
// =====
// Take an enabled physical IRQ exception.

AArch32.TakePhysicalIRQException()

    route_to_monitor = HaveEL(EL3) && SCR_GEN[].IRQ == '1';
    take_to_hyp = PSTATE.EL == EL2;
    route_to_hyp = (AArch32.GeneralExceptionsToHyp() ||
        (HaveEL(EL2) && !IsSecure() && HCR.IMO == '1'));

    if AArch32.ExceptionToAArch64(route_to_monitor, route_to_hyp) then
        AArch64.TakePhysicalIRQException();

    vect_offset = 0x18;
    bits(32) preferred_exception_return = ThisInstrAddr();
    lr_offset = 4;

    if route_to_monitor then
        AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);
    elseif take_to_hyp || route_to_hyp then
        exception = ExceptionSyndrome(Exception_IRQ);
        AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
    else
        AArch32.EnterMode(M32_IRQ, preferred_exception_return, lr_offset, vect_offset);
```

*Additional pseudocode functions for exception handling on page G1-3491* defines the EnterMonitorMode() and EnterHypMode() pseudocode procedures.

### G1.13.11 Virtual IRQ exception

The Virtual IRQ exception is implemented only as part of EL2.

A Virtual IRQ exception is generated if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of [CPSR.I](#) is 0.
- Either:
  - EL2 is using AArch32 and the value of [HCR.IMO](#) is 1.
  - EL2 is using AArch64 and the value of [HCR\\_EL2.IMO](#) is 1.
- One of the following applies:
  - EL2 is using AArch32 and the value of [HCR.VI](#) is 1.
  - EL2 is using AArch64 and the value of [HCR\\_EL2.VI](#) is 1.
  - A Virtual IRQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The conditions for generating a Virtual IRQ exception mean the exception is always:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure IRQ mode.

For more information see *Virtual exceptions when an implementation includes EL2 on page G1-3465*

The preferred return address for a Virtual IRQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. This return is performed using the [SPSR](#) and [LR\\_irq](#) values generated by the exception entry, using an exception return instruction with a subtraction of 4.

## Pseudocode description of taking the Virtual IRQ exception

The TakeVirtualIRQException() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeVirtualIRQException()
// =====

AArch32.TakeVirtualIRQException()
    assert HaveEL(EL2) && !IsSecure() && PSTATE.EL != EL2 && HCR.TGE == '0';

    if !ELUsingAArch32(EL1) then
        AArch64.TakeVirtualFIQException();

    vect_offset = 0x18;
    bits(32) preferred_exception_return = ThisInstrAddr();
    lr_offset = 4;

    AArch32.EnterMode(M32_IRQ, preferred_exception_return, lr_offset, vect_offset);
```

### G1.13.12 FIQ exception

The FIQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an FIQ interrupt request input to the PE.

When an FIQ exception is taken, exception entry is precise to an instruction boundary.

As described in *Asynchronous exception masking controls on page G1-3468*, FIQ exceptions can be masked. When this happens, a generated FIQ exception is not taken until it is not masked.

By default, an FIQ exception is taken to FIQ mode, but an FIQ exception can be taken:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information, see *Determining the PE mode to which the physical FIQ exception is taken on page G1-3449*.

The preferred return address for an FIQ exception is the address of the instruction following the instruction boundary at which the exception was taken. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the *SPSR* and *LR* values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - *SPSR\_fiq* and *LR\_fiq* if returning from FIQ mode.
  - *SPSR\_mon* and *LR\_mon* if returning from Monitor mode.
- If returning from Hyp mode, using the *SPSR\_hyp* and *ELR\_hyp* values generated by the exception entry, using an ERET instruction.

For more information, see *Exception return to an Exception level using AArch32 on page G1-3454*.

## Pseudocode description of taking the FIQ exception

The TakePhysicalFIQException() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakePhysicalFIQException()
// =====

AArch32.TakePhysicalFIQException()

    route_to_monitor = HaveEL(EL3) && SCR_GEN[].FIQ == '1';
    take_to_hyp = PSTATE.EL == EL2;
    route_to_hyp = (AArch32.GeneralExceptionsToHyp() ||
        (HaveEL(EL2) && !IsSecure() && HCR.FMO == '1'));

    if AArch32.ExceptionToAArch64(route_to_monitor, route_to_hyp) then
        AArch64.TakePhysicalFIQException();
```

```
vect_offset = 0x1C;
bits(32) preferred_exception_return = ThisInstrAddr();
lr_offset = 4;

if route_to_monitor then
    AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);
elseif take_to_hyp || route_to_hyp then
    exception = ExceptionSyndrome(Exception_FIQ);
    AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
else
    AArch32.EnterMode(M32_FIQ, preferred_exception_return, lr_offset, vect_offset);
```

*Additional pseudocode functions for exception handling on page G1-3491* defines the `EnterMonitorMode()` and `EnterHypMode()` pseudocode procedures.

### G1.13.13 Virtual FIQ exception

The Virtual FIQ exception is implemented only as part of EL2.

A Virtual FIQ exception is generated if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of `CPSR.F` is 0.
- Either:
  - EL2 is using AArch32 and the value of `HCR.FMO` is 1.
  - EL2 is using AArch64 and the value of `HCR_EL2.IMO` is 1.
- One of the following applies:
  - EL2 is using AArch32 and the value of `HCR.VF` is 1.
  - EL2 is using AArch64 and the value of `HCR_EL2.VF` is 1.
  - A Virtual FIQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The conditions for generating a Virtual FIQ exception mean the exception is always:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure FIQ mode.

For more information see *Virtual exceptions when an implementation includes EL2 on page G1-3465*.

The preferred return address for a Virtual FIQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. This return is performed using the `SPSR` and `LR_irq` values generated by the exception entry, using an exception return instruction with a subtraction of 4.

#### Pseudocode description of taking the Virtual FIQ exception

The `TakeVirtualFIQException()` pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeVirtualFIQException()
// =====

AArch32.TakeVirtualFIQException()
    assert HaveEL(EL2) && !IsSecure() && PSTATE.EL != EL2 && HCR.TGE == '0';

    if !ELUsingAArch32(EL1) then
        AArch64.TakeVirtualFIQException();

    vect_offset = 0x1C;
    bits(32) preferred_exception_return = ThisInstrAddr();
    lr_offset = 4;

    AArch32.EnterMode(M32_FIQ, preferred_exception_return, lr_offset, vect_offset);
```

### G1.13.14 Additional pseudocode functions for exception handling

The EnterMonitorMode() pseudocode function changes the PE mode to Monitor mode, with the required state changes:

```
// AArch32.EnterMonitorMode()
// =====
// Take an exception to Monitor mode.

AArch32.EnterMonitorMode(bits(32) preferred_exception_return, integer lr_offset,
                          integer vect_offset)
  assert HaveEL(EL3) && ELUsingAArch32(EL3);

  spsr = GetSPSRFromPSTATE();
  if PSTATE.M == M32_Monitor then SCR.NS = '0';
  AArch32.WriteMode(M32_Monitor);
  SPSR[] = spsr;
  R[14] = preferred_exception_return + lr_offset;
  PSTATE.J = '0';
  PSTATE.T = SCTLR.TE;
  PSTATE.E = SCTLR.EE;
  PSTATE.<A,I,F> = '111';
  PSTATE.IT = '00000000';
  BranchTo(MVBAR + vect_offset, BranchType_UNKNOWN);
```

The EnterHypMode() pseudocode function changes the PE mode to Hyp mode, with the required state changes:

```
// AArch32.EnterHypMode()
// =====
// Take an exception to Hyp mode.

AArch32.EnterHypMode(ExceptionRecord exception, bits(32) preferred_exception_return,
                      integer vect_offset)
  assert HaveEL(EL2) && !IsSecure() && ELUsingAArch32(EL2);

  spsr = GetSPSRFromPSTATE();
  AArch32.WriteMode(M32_Hyp);
  if !(exception.type IN {Exception_IRQ, Exception_FIQ}) then
    AArch32.ReportHypEntry(exception);
  SPSR[] = spsr;
  R[14] = preferred_exception_return;
  PSTATE.J = '0';
  PSTATE.T = HSCTLR.TE;
  PSTATE.E = HSCTLR.EE;
  if !HaveEL(EL3) || SCR_GEN[].EA == '0' then PSTATE.A = '1';
  if !HaveEL(EL3) || SCR_GEN[].IRQ == '0' then PSTATE.I = '1';
  if !HaveEL(EL3) || SCR_GEN[].FIQ == '0' then PSTATE.F = '1';
  PSTATE.IT = '00000000';
  BranchTo(HVBAR + vect_offset, BranchType_UNKNOWN);
```

## G1.14 The conceptual coprocessor interface and system control

AArch32 state includes a coprocessor interface that can access sixteen coprocessors, CP0 to CP15. [Coprocessor support on page E1-2331](#) introduces this interface. Part of this interface is reserved for conceptual coprocessors, as follows:

- CP10 and CP11 provide Advanced SIMD and floating-point functionality.
- CP14 and CP15 provide configuration and control related to the architecture:

In ARMv8, AArch32 has no support for coprocessors other than CP10, CP11, CP14, and CP15.

This section gives:

- An introduction to the CP14 and CP15 registers, see [CP14 and CP15 system control registers](#).
- Information about access controls for the other coprocessors, see [Access controls on CP10 and CP11](#).

### G1.14.1 CP14 and CP15 system control registers

In AArch32 state:

- CP14 is reserved for the configuration and control of:
  - Debug features, see [Debug registers on page G4-4101](#).
  - Trace features, see the [Embedded Trace Macrocell Architecture Specification](#) and the [CoreSight Program Flow Trace Architecture Specification](#).
  - The T32 Execution Environment, if implemented. In ARMv8, T32EE is OPTIONAL and deprecated.
  - Identification registers for the Trivial Jazelle implementation, see [Trivial implementation of the Jazelle extension on page G1-3429](#).
- CP15 is called the System Control coprocessor, and is reserved for the control and configuration of the PE, including architecture and feature identification. This means CP15 provides access to the System registers that control and return status information for PE operation in non-debug state.

See [Chapter G4 AArch32 System Register Descriptions](#).

#### Access to CP14 and CP15 registers

Most CP14 and CP15 registers are accessible only from EL1 or higher. For possible accesses from EL0:

- The register descriptions in [Chapter G4 AArch32 System Register Descriptions](#) indicate whether a register is accessible from EL0.

———— **Note** —————

These chapters provide all of the CP14 and CP15 register descriptions in this manual, except for the CP14 debug registers, that are described in [Debug registers on page G4-4101](#).

- The descriptions of the CP14 interface in [Debug registers on page G4-4101](#) include the permitted accesses to the debug registers from EL0.
- [EL0 views of the CP15 registers on page G3-3732](#) summarizes the permitted accesses to CP15 registers from EL0.

### G1.14.2 Access controls on CP10 and CP11

The CP10 and CP11 part of the coprocessor interface supports the Advanced SIMD and floating-point instructions, providing access to System registers relating to the use of these instructions, and some instruction encodings. See also [Advanced SIMD and floating-point support on page G1-3494](#).

In ARMv8, the CPACR controls access to CP10 and CP11 from software executing at EL1 or EL0 in AArch32 state.

Initially on powerup or reset into AArch32 state, access to coprocessors CP10 and CP11 is disabled.

---

**Note**

The **CPACR** has no effect on accesses from Hyp mode.

---

If an implementation includes EL3, the **NSACR** determines whether CP10 and CP11 can be accessed from the Non-secure state.

If an implementation includes EL2, the **HCPTR** provides additional controls on Non-secure accesses to CP10 and CP11. For accesses that are otherwise permitted by the **CPACR** and **NSACR** settings, setting **HCPTR** bits to 1:

- Traps otherwise-permitted accesses from EL1 or EL0 to EL2. When EL2 is using AArch32, these accesses are trapped to Hyp mode.
- Makes accesses from EL2 mode UNDEFINED. When EL2 is using AArch32, this makes accesses from Hyp mode UNDEFINED.

For more information, see [Trapping accesses to coprocessors on page G1-3511](#).

---

**Note**

The access settings for CP10 and CP11 must be identical. If these settings are not identical the behavior of the Advanced SIMD and floating-point functionality is CONstrained UNPREDICTABLE. ARMv8 constrains the UNPREDICTABLE behavior to be that, for all purposes other than reading the value of the field, behavior is as if the access control field for CP11 has the same value as the access control field for CP10.

---

## G1.15 Advanced SIMD and floating-point support

[Advanced SIMD and floating-point instructions on page E1-2303](#) introduces:

- The scalar floating-point instructions in the A32 and T32 instruction sets.
- The Advanced SIMD integer and floating-point vector instructions in the A32 and T32 instruction sets.
- The Advanced SIMD and floating-point registers file D0 - D31, and its alternative views as S0 - S31 and Q0 - Q15.
- The *Floating-Point Status and Control Register (FPSCR)*.

For more information about the system registers for the Advanced SIMD and floating-point operation see [Advanced SIMD and floating-point system registers on page G1-3500](#). Software can interrogate these registers to discover the implemented Advanced SIMD and floating-point support.

The following subsections give more information about the Advanced SIMD and Floating-point support:

- [Enabling Advanced SIMD and floating-point support](#).
- [Advanced SIMD and floating-point system registers on page G1-3500](#).
- [Context switching when using Advanced SIMD and floating-point functionality on page G1-3501](#).
- [Floating-point exception traps, serialization, and floating-point exception barriers on page G1-3501](#).

### G1.15.1 Enabling Advanced SIMD and floating-point support

Software must ensure that the required access to the Advanced SIMD and floating-point features is enabled:

- Any use of Advanced SIMD or floating-point features requires access to CP10 and CP11.
- Additional controls apply to the use of Advanced SIMD features, see [Additional controls on Advanced SIMD functionality on page G1-3498](#).

#### ———— **Note** —————

This section describes the controls when the controlling Exception levels are using AArch32. Similar controls are provided when the Exception levels are using AArch64, and then apply to lower Exception levels that are using AArch32.

The controls of access to CP10 and CP11 are:

- **CPACR**.{cp10, cp11} control access from PE modes other than Hyp mode. The permitted values of these fields are:
  - 0b00** No access. Any access to the Advanced SIMD and floating-point features is UNDEFINED.
  - 0b01** Accessible from privileged modes only. Any access to the Advanced SIMD and floating-point features from User mode is UNDEFINED.
  - 0b11** Accessible from privileged and unprivileged modes.These fields reset to 0b00, no access.  
These fields have no effect on accesses to CP10 and CP11 from Hyp mode.
- In an implementation that includes EL3, **NSACR**.{cp10, cp11} control access from Non-secure state. The permitted values of these bits are:
  - 0** Accessible from Secure state only. Any access to the Advanced SIMD and floating-point features from Non-secure state is UNDEFINED.
  - 1** Accessible from both Security states, subject to any other access controls that apply. These include:
    - For accesses from any PE mode other than Hyp mode, the **CPACR**.{cp10, cp11} controls.
    - If the implementation includes EL2, the **HCPTR**.{TCP10, TCP11} control. This applies to accesses from all PE modes in Non-secure state.

- In an implementation that includes EL2, when **NSACR**.{cp10, cp11} are set to 1, to permit Non-secure accesses, **HCPTR**.{TCP10, TCP11} provide an additional control on those accesses. The permitted values of these bits are:
  - 0** Advanced SIMD and floating-point features are accessible from Non-secure state, subject to any other access controls that apply. The **CPACR**.{cp10, cp11} controls:
    - Have no effect on accesses from Hyp mode.
    - Apply to accesses from all other PE modes.
  - 1** Trap coprocessor accesses:
    - Any access from a Non-secure PE mode other than Hyp mode that is permitted by other controls, including the **CPACR**.{cp10, cp11} controls, generates an exception that is taken to Hyp mode.
    - Any access to Advanced SIMD and floating-point features from Hyp mode is UNDEFINED.

When **NSACR**.{cp10, cp11} are set to 0, all accesses to Advanced SIMD and floating-point features from Non-secure state are UNDEFINED.

———— **Note** ————

The **HCPTR** can also trap to Hyp mode otherwise-permitted Non-secure EL1 and EL0 accesses to Advanced SIMD and floating-point functionality. At reset, those traps are disabled.

Access control bits for CP10 and CP11 must be programmed with the same values, otherwise operation of the controlled Advanced SIMD and floating-point features is CONstrained UNPREDICTABLE. This means that operation is CONstrained UNPREDICTABLE:

- In any implementation, if the values of **CPACR**.cp10 and **CPACR**.cp11 are different.
- In an implementation that includes EL3, in Non-secure state, if the values of **NSACR**.cp10 and **NSACR**.cp11 are different.
- In an implementation that includes EL2, in Non-secure state, if the values of **HCPTR**.TCP10 and **HCPTR**.TCP11 are different.

In ARMv8, the CONstrained UNPREDICTABLE behavior is that, for all purposes other than reading the value of the register field, behavior is as if the access control field for CP11 has the same value as the access control field for CP10.

In addition, **FPEXC**.EN is an enable bit for most Advanced SIMD and floating-point operations. When **FPEXC**.EN is 0, all Advanced SIMD and floating-point instructions are treated as UNDEFINED except for:

- A VMSR to the **FPEXC** or **FPSID** register.
- A VMRS from the **FPEXC**, **FPSID**, **MVFR0**, or **MVFR1** register.

These instructions can be executed only at EL1 or higher.

———— **Note** ————

- Although **FPSID** is a read-only register, software can perform a VMSR to the **FPSID** to force Floating-point serialization, as described in *Floating-point exception traps, serialization, and floating-point exception barriers on page G1-3501*.
- When **FPEXC**.EN is 0, these operations are treated as UNDEFINED:
  - A VMSR to the **FPSCR**.
  - A VMRS from the **FPSCR**.

These controls, summarized in *Summary of general controls of CP10 and CP11 functionality on page G1-3496*, apply to all functionality that depends on access to CP10 and CP11. That is, they apply equally to all implemented Advanced SIMD and floating-point functionality.

Additional controls apply to any implemented Advanced SIMD functionality, see *Additional controls on Advanced SIMD functionality on page G1-3498*.

[Pseudocode details of enabling the Advanced SIMD and Floating-point Extensions on page G1-3499](#) gives a pseudocode description of both sets of controls.

### Summary of general controls of CP10 and CP11 functionality

Table G1-21 summarizes the access controls for the implemented Advanced SIMD and floating-point functionality, that are based on controlling access to coprocessors CP10 and CP11, and on the `FPEXC.EN` enable bit. The following subsections give more information about the entries in this table:

- [Information about the general controls of CP10 and CP11 functionality on page G1-3497](#).
- [EL0 access to Advanced SIMD and floating-point functionality on page G1-3497](#).

In this table, and in [Table G1-22 on page G1-3498](#), an entry of:

- `UND` indicates that the Advanced SIMD or floating-point access generates an Undefined Instruction exception. For an access made from Hyp mode this exception is taken to Hyp mode, otherwise it is taken to Secure or Non-secure Undefined mode.
- `Trapped` indicates that accesses generate a Hyp Trap exception, that is taken to Hyp mode.

**Table G1-21 Summary of access controls for all CP10 and CP11 functionality**

Controls				Secure		Non-secure			
<code>CPACR.cpn<sup>a</sup></code>	<code>NSACR.cpn</code>	<code>HCPTR.TCP<sup>n</sup></code>	<code>FPEXC.EN</code>	<code>EL3<sup>b</sup></code>	<code>EL0</code>	<code>EL2</code>	<code>EL1</code>	<code>EL0</code>	
00	0	x <sup>c</sup>	x	UND	UND	UND	UND	UND	
			0	UND	UND	UND <sup>d</sup>	UND	UND	
	1	0	0	UND	UND	Enabled	UND	UND	
			1	UND	UND	UND	UND	UND	
01	0	x <sup>c</sup>	0	UND <sup>d</sup>	UND	UND	UND	UND	
			1	Enabled	UND	UND	UND	UND	
			0	UND <sup>d</sup>	UND	UND <sup>d</sup>	UND <sup>d</sup>	UND	
	1	0	0	UND <sup>d</sup>	UND	UND	UND	UND <sup>e</sup>	UND
			1	Enabled	UND	Enabled	Enabled	UND	
			0	UND <sup>d</sup>	UND	UND	Trapped	UND	
11	0	x <sup>c</sup>	0	UND <sup>d</sup>	UND	UND	UND	UND	
			1	Enabled	Enabled	UND	UND	UND	
			0	UND <sup>d</sup>	UND	UND <sup>d</sup>	UND <sup>d</sup>	UND	
	1	0	0	UND <sup>d</sup>	UND	UND	UND	UND <sup>e</sup>	UND
			1	Enabled	Enabled	Enabled	Enabled	Enabled	
			0	UND <sup>d</sup>	UND	UND	UND <sup>e</sup>	UND	
1	1	0	UND <sup>d</sup>	UND	UND	UND	UND <sup>e</sup>	UND	
		1	Enabled	Enabled	UND	Trapped	Trapped		

- When the corresponding `NSACR` bit is set to 0, for Non-secure accesses the `CPACR` field behaves as RAZ/WI. That is, when `NSACR.cp10` is set to 0, for Non-secure accesses `CPACR.cp10` ignores writes, and reads as `0b00`, regardless of its actual value.
- When `EL3` is implemented and is using AArch64, Monitor mode is not available, and all Secure modes other than User mode are Secure `EL1` modes.
- When the `NSACR` control bits are set to 0, for Non-secure accesses the `HCPTR` control bits behave as RAO/WI.
- Except for `VMSR` to the `FPEXC` or `FPSID` register, or a `VMRS` from the `FPEXC`, `FPSID`, `MVFR0`, or `MVFR1` register.

- e. Except for VMSR to the **FPEXC** or **FPSID** register, or a VMRS from the **FPEXC**, **FPSID**, **MVFR0**, or **MVFR1** register, that are Trapped.

———— **Note** —————

In [Table G1-21 on page G1-3496](#):

- The behavior of Secure accesses depends only on the **CPACR** and **FPEXC** control values.
- The behavior of accesses from Hyp mode depends only on the **NSACR**, **HCPTR**, and **FPEXC** control values.

**Information about the general controls of CP10 and CP11 functionality**

In [Table G1-21 on page G1-3496](#), the values for each of the registers shown in the *Controls* columns are:

**CPACR** The value of the **CPACR**.{cp10, cp11} fields. These fields must be programmed to the same value, otherwise behavior is CONSTRAINED UNPREDICTABLE. The table does not show the reserved value of 0b10.

**NSACR** The value of the **NSACR**.{cp10, cp11} bits. These bits must be programmed to the same value, otherwise behavior is CONSTRAINED UNPREDICTABLE.

These controls are implemented only as part of EL3. For the access controls for an implementation that does not include EL3, consider only:

- The Secure EL3 and EL0 columns. When EL3 is not implemented:
  - Monitor mode is not available.
  - There is only a single Security state, and all AArch32 modes other than User mode and Hyp mode are always EL1 modes.
- The rows for which **NSACR** is 0, and **HCPTR** is 0 or x.

**HCPTR** The value of the **HCPTR**.{TCP10, TCP11} bits. These bits must be programmed to the same value, otherwise behavior is CONSTRAINED UNPREDICTABLE.

These controls are implemented only as part of EL2. For the access controls for an implementation that does not include EL2:

- Ignore the Non-secure EL2 column.
- Consider only the rows for which **HCPTR** is 0 or x.

**FPEXC.EN** The value of **FPEXC**.EN. As indicated in this section, and in the table footnote, when this bit is set to 0:

- Most Advanced SIMD and floating-point functionality is disabled.
- A limited number of register accesses are permitted at EL1 or higher.

When this bit is set to 1, Advanced SIMD and floating-point functionality is enabled, but subject to:

- The other access controls shown in the table.
- The restrictions described in [EL0 access to Advanced SIMD and floating-point functionality](#).

In ARMv8, the CONSTRAINED UNPREDICTABLE behavior when the access control fields for CP10 and CP11 have different values is that, for all purposes other than reading the value of the register field, behavior is as if the access control field for CP11 has the same value as the access control field for CP10.

**EL0 access to Advanced SIMD and floating-point functionality**

When [Table G1-21 on page G1-3496](#) shows that EL0 access to the Advanced SIMD and floating-point functionality is enabled, this applies only to the subset of functionality that is available at EL0. In particular, the only Advanced SIMD and Floating-point system register that is accessible is the **FPSCR**. However, the Advanced SIMD and floating-point instructions are available. Execution at EL0 corresponds to the application level view of the extensions, as described in [Advanced SIMD and Floating-point system registers on page E1-2306](#).

### Additional controls on Advanced SIMD functionality

If the general controls summarized in [Summary of general controls of CP10 and CP11 functionality on page G1-3496](#) permit access to CP10 and CP11 functionality, additional controls apply to any implemented Advanced SIMD functionality. The following controls apply to all Advanced SIMD instructions, that is, to all instruction encodings in [Alphabetical list of T32 and A32 base instruction set instructions on page F7-2534](#) that are identified as Advanced SIMD encodings and are not also floating-point encodings:

- When the value of **CPACR.ASEDIS** is 1, all Advanced SIMD instructions are UNDEFINED.
- In an implementation that includes EL3, when the value of **CPACR.ASEDIS** is 0, if the value of **NSACR.NSASEDIS** is 1 and the PE is in Non-secure state, **CPACR.ASEDIS** appears as RAO/WI and all Advanced SIMD instructions are UNDEFINED.
- In an implementation that includes EL2, when the **CPACR** and **NSACR** settings permit Non-secure use of the Advanced SIMD instructions, if **HCPTR.TASE** is set to 1 any use of an Advanced SIMD instruction from:
  - A Non-secure EL1 or EL0 mode is trapped to Hyp mode.
  - Hyp mode generates an Undefined Instruction exception that is taken to Hyp mode.

[Table G1-22](#) references the descriptions of the registers that control this functionality, and [Summary of access controls for Advanced SIMD functionality](#) shows these controls.

### Summary of access controls for Advanced SIMD functionality

[Table G1-22](#) summarizes the additional access controls for the use of Advanced SIMD instructions.

- In this table, entries of UND and Enabled have the meanings defined in [Summary of general controls of CP10 and CP11 functionality on page G1-3496](#)
- The entries shown in this table must be combined with the information shown in [Table G1-21 on page G1-3496](#) as follows:
  - If at least one table shows the access as UND then the access is UNDEFINED.
  - Otherwise, if at least one table shows the access as Trapped then the access generates a Hyp Trap exception.
  - Otherwise, both tables show the access as Enabled, meaning the access is permitted.

**Table G1-22 Summary of additional access controls for Advanced SIMD functionality**

Controls			Secure		Non-secure		
<b>CPACR.ASEDIS</b>	<b>NSACR.NSASEDIS</b>	<b>HCPTR.TASE</b>	<b>EL3<sup>a</sup></b>	<b>EL0</b>	<b>EL2</b>	<b>EL1</b>	<b>EL0</b>

		1	UND	UND	UND	UND	UND
	1	x <sup>b</sup>	UND	UND	UND	UND	UND

a. When EL3 is implemented and is using AArch64, Monitor mode is not available, and all Secure modes other than User mode are Secure EL1 modes.

b. When the value of the **NSACR.NSASEDIS** is 1, for Non-secure accesses:

- To **CPACR**, the **ASEDIS** bit behaves as RAO/WI.
- To **HCPTR**, the **TASE** bit behaves as RAO/WI.

When interpreting [Table G1-22 on page G1-3498](#):

- The **NSACR** is implemented only as part of EL3. For an implementation that does not include EL3, use of the Advanced SIMD instructions:
  - Is enabled when **CPACR.ASEDIS** is set to 0.
  - Is disabled when **CPACR.ASEDIS** is set to 1.
- The **HCPTTR** is implemented only as part of EL2. For an implementation that does not include EL2, when the controls shown in [Table G1-21 on page G1-3496](#) permit Non-secure use of the CP10 and CP11 functionality, use of the Advanced SIMD instructions from Non-secure state:
  - Is enabled when **CPACR.ASEDIS** and **NSACR.NSASEDIS** are both set to 0.
  - Is disabled otherwise.

## Pseudocode details of enabling the Advanced SIMD and Floating-point Extensions

The following pseudocode takes appropriate action if an Advanced SIMD or Floating-point instruction is used when the extensions are not enabled:

```
// CheckAdvSIMDOrVFPEEnabled()
// =====

CheckAdvSIMDOrVFPEEnabled(boolean include_fpxc_check, boolean advsimd)
    instr = ThisInstr();
    AArch32.CheckAdvSIMDOrFPEEnabled(include_fpxc_check, advsimd, instr);
    // Return from CheckAdvSIMDOrFPEEnabled() occurs only if VFP access is permitted
    return;

// AArch32.CheckAdvSIMDOrFPEEnabled()
// =====
// Check against CPACR, FPEXC, HCPTTR, NSACR, and CPTR_EL3.

AArch32.CheckAdvSIMDOrFPEEnabled(boolean fpxc_check, boolean advsimd, bits(32) instr)

    if !ELUsingAArch32(EL1) then
        AArch64.CheckFPAdvSIMDEnabled();
    else
        cpacr_asedis = CPACR.ASEDIS;
        cpacr_cp10 = CPACR.cp10;

        if HaveEL(EL2) && !IsSecure() then
            hcptr_tase = if ELUsingAArch32(EL2) then HCPTTR.TASE else '0';
            hcptr_cp10 = HCPTTR.TCP10;

        if HaveEL(EL3) && ELUsingAArch32(EL3) && !IsSecure() then
            // Check if access disabled in NSACR
            if NSACR.NSASEDIS == '1' then
                cpacr_asedis = '1';
                if HaveEL(EL2) then hcptr_tase = '1';
            if NSACR.cp10 == '0' then
                cpacr_cp10 = '00';
                if HaveEL(EL2) then hcptr_cp10 = '1';

        if PSTATE.EL != EL2 then
            // Check if Advanced SIMD disabled in CPACR
            if advsimd && cpacr_asedis == '1' then
                AArch32.AdvSIMDFPAccessTrap(EL1, advsimd, instr);

            // Check if access disabled in CPACR
            if cpacr_cp10<0> == '0' || (cpacr_cp10<1> == '0' && PSTATE.EL == EL0) then
                AArch32.AdvSIMDFPAccessTrap(EL1, advsimd, instr);

        // If required, check FPEXC enabled bit. If EL1 is using AArch64, then do not
        // make this check
        if fpxc_check && FPEXC.EN == '0' then UNDEFINED;
```

```
    if HaveEL(EL2) && !IsSecure() then
        // Check if Advanced SIMD access disabled in HCPTR
        if advsimd && hcptr_tase == '1' then
            AArch32.AdvSIMDFPAccessTrap(EL2, advsimd, instr);

        // Check if access disabled in HCPTR
        if hcptr_cp10 == '1' then
            AArch32.AdvSIMDFPAccessTrap(EL2, advsimd, instr);

    if HaveEL(EL3) && !ELUsingAArch32(EL3) then
        // Check if access disabled in CPTR_EL3
        if CPTR_EL3.TFP == '1' then
            AArch64.AdvSIMDFPAccessTrap(EL3);

    return;

// CheckAdvSIMDEnabled()
// =====

CheckAdvSIMDEnabled()

    fpxc_check = TRUE;
    advsimd = TRUE;
    instr = ThisInstr();

    AArch32.CheckAdvSIMDOrFPEEnabled(fpxc_check, advsimd, instr);
    // Return from CheckAdvSIMDOrFPEEnabled() occurs only if Advanced SIMD access is permitted

    // Make temporary copy of D registers
    // _Dclone[] is used as input data for instruction pseudocode
    for i = 0 to 31
        _Dclone[i] = D[i];

    return;

// CheckVFPEEnabled()
// =====

CheckVFPEEnabled(boolean include_fpxc_check)
    advsimd = FALSE;
    instr = ThisInstr();
    AArch32.CheckAdvSIMDOrFPEEnabled(include_fpxc_check, advsimd, instr);
    // Return from CheckAdvSIMDOrFPEEnabled() occurs only if VFP access is permitted
    return;
```

## G1.15.2 Advanced SIMD and floating-point system registers

AArch32 state provides a common set of System registers for the Advanced SIMD and floating-point functionality. This section gives general information about this set of registers, and indicates where each register is described in detail. It contains the following subsections:

- [Register map of the Advanced SIMD and floating-point System registers.](#)
- [Accessing the Advanced SIMD and floating-point System registers on page G1-3501.](#)

### Register map of the Advanced SIMD and floating-point System registers

[Table G1-24 on page G1-3506](#) shows the register map of the Advanced SIMD and Floating-point registers. Each register is 32 bits wide. In an implementation that includes EL3, the Advanced SIMD and Floating-point registers are common registers, see [Common System registers on page G3-3702](#).

## Accessing the Advanced SIMD and floating-point System registers

Software accesses the Advanced SIMD and floating-point System registers using the VMRS and VMSR instructions, see:

- [VMRS on page F7-3070](#).
- [VMSR on page F7-3072](#).

For example:

```
VMRS <Rt>, FPSID    ; Read Floating-Point System ID Register
VMRS <Rt>, MVFR1    ; Read Media and VFP Feature Register 1
VMSR FPSCR, <Rt>    ; Write Floating-Point System Control Register
```

Software can access the Advanced SIMD and floating-point System registers only if the access controls permit the access, see [Enabling Advanced SIMD and floating-point support on page G1-3494](#).

### ———— Note ————

All hardware ID information can be accessed only from EL1 or higher. This means:

#### **The FPSID is accessible only from EL1 or higher.**

This is a change introduced from VFPv3. Previously, the [FPSID](#) register can be accessed in all modes.

#### **The MVFR registers are accessible only from EL1 or higher.**

Unprivileged software must issue a system call to determine what features are supported.

## G1.15.3 Context switching when using Advanced SIMD and floating-point functionality

When the Advanced SIMD and floating-point functionality is used by only a subset of processes, the operating system might implement lazy context switching of the Advanced SIMD and floating-point register file and System registers.

In the simplest lazy context switch implementation, the primary context switch software disables the Advanced SIMD and floating-point functionality, by disabling access to coprocessors CP10 and CP11 in the [CPACR](#), see [Enabling Advanced SIMD and floating-point support on page G1-3494](#). Subsequently, when a process or thread attempts to use an Advanced SIMD or Floating-point instruction, it triggers an Undefined Instruction exception. The operating system responds by saving and restoring the Advanced SIMD and floating-point register file and System registers. Typically, it then re-executes the Advanced SIMD or floating-point instruction that generated the Undefined Instruction exception.

## G1.15.4 Floating-point exception traps, serialization, and floating-point exception barriers

Execution of a floating-point instruction can generate an exceptional condition, called a *floating-point exception*.

### ———— Note ————

Do not confuse floating-point exceptions with the AArch32 architectural exceptions summarized in [AArch32 state exception descriptions on page G1-3475](#).

An Advanced SIMD and floating-point implementation can support floating-point exception *traps*, meaning floating-point exceptions are passed back to application software to resolve, see [Floating-point exceptions on page E1-2307](#).

VMRS and VMSR instructions that access the [FPSID](#), [FPSCR](#), or [FPEXC](#) registers are *serializing* instructions. This means that, before they perform any required register transfer, they ensure that any exceptional condition that requires support code processing, from any preceding Floating-point instruction, has been detected and reflected in the extension system registers. A VMSR instruction to the read-only [FPSID](#) register is a serializing NOP.

In addition, a VMRS or VMSR instruction that accesses the [FPSCR](#) acts as a *Floating-point exception barrier*. This means that, before it performs the register transfer, it ensures that any outstanding exceptional conditions in preceding Floating-point instructions have been detected and processed by the support code. If necessary, the VMRS or VMSR instruction takes an asynchronous bounce to force the processing of any outstanding exceptional conditions.

In pseudocode, Floating-point serialization and the Floating-point exception barriers are described by the `SerializeVFP()` and `VFPExcBarrier()` functions respectively.

## G1.16 AArch32 control of traps to the hypervisor

This section describes the traps provided by EL2, that software executing at EL2 can use to trap Non-secure operations performed at EL1 or EL0. This section describes the control of these traps when EL2 is using AArch32, meaning the traps must be configured by software executing in Hyp mode. When EL2 is using AArch32:

- The Non-secure EL1 and EL0 exceptions must also be using AArch32,
- The traps to EL2 are taken to Hyp mode.

In addition, software executing in Hyp mode can route a number of exceptions to be taken to Hyp mode, provided EL3 controls are not routing them to be taken at EL3. Therefore, the trapping and related mechanisms provided by EL2 include:

- Trapping attempted execution of certain instructions to Hyp mode, so a hypervisor can emulate the instruction. This section describes these traps.
  - Routing certain synchronous exceptions to Hyp mode, see:
    - [Routing general exceptions to EL2 on page G1-3452.](#)
    - [Routing Debug exceptions to Hyp mode on page G1-3454.](#)
- **Note** —————
- These controls for routing synchronous exceptions to Hyp mode are similar to the controls for the traps described in this section, and [Summary of trap controls on page G1-3517](#) includes these trap controls.
  - In addition, a hypervisor can route interrupts and asynchronous external aborts to itself. For more information see [Asynchronous exception routing controls on page G1-3467.](#)
- 
- Providing aliased versions of some system control registers, see [Trapping ID mechanisms on page G1-3506.](#)

Because of the wide range of usage models for virtualization, EL2 provides many trapping options, supporting different levels of granularity of the trapping. The following sections describe these trapping options:

- [General information about traps to the hypervisor on page G1-3504.](#)
- [Trapping ID mechanisms on page G1-3506.](#)
- [Trapping accesses to lockdown, DMA, and TCM operations on page G1-3508.](#)
- [Trapping accesses to cache maintenance operations on page G1-3509.](#)
- [Trapping accesses to TLB maintenance operations on page G1-3509.](#)
- [Trapping accesses to the Auxiliary Control Register on page G1-3509.](#)
- [Trapping accesses to the Performance Monitors Extension on page G1-3510.](#)
- [Trapping use of the SMC instruction on page G1-3510.](#)
- [Trapping use of the WFI and WFE instructions on page G1-3511.](#)
- [Trapping accesses to the T32EE configuration registers on page G1-3511.](#)
- [Trapping accesses to coprocessors on page G1-3511.](#)
- [Trapping writes to virtual memory control registers on page G1-3513.](#)
- [Generic trapping of accesses to CP15 system control registers on page G1-3513.](#)
- [Trapping CP14 accesses to debug registers on page G1-3514.](#)
- [Trapping CP14 accesses to trace registers on page G1-3516.](#)
- [Summary of trap controls on page G1-3517.](#)

———— **Note** —————

Many of these sections include a Note that indicates when or why a hypervisor might use the traps described in that section. This information is not part of the architecture specification.

These sections include descriptions of trapping Debug configuration options that can generate traps when the PE is in Non-debug state. EL2 does not provide any trapping in Debug state.

## G1.16.1 General information about traps to the hypervisor

The Hyp Trap exception provides the standard mechanism for trapping Guest OS functions to the hypervisor. When EL2 is using AArch32, the PE always takes a Hyp Trap exception to Hyp mode, and enters the exception handler using the vector at offset 0x14 from the Hyp vector base address. For more information see [Handling exceptions that are taken to an Exception level using AArch32 on page G1-3431](#).

When the PE enters the handler for a Hyp Trap exception, the HSR holds syndrome information for the exception. For more information see [Use of the HSR on page G3-3672](#).

A Hyp Trap exception can be generated only when all of the following apply:

- The PE is both:
  - Not in Debug state.
  - In a Non-secure EL1 or EL0 mode.
- The trapped instruction is not UNPREDICTABLE in the mode in which it is executed. UNPREDICTABLE instructions can generate a Hyp Trap exception, but the architecture does not require them to do so, see [UNPREDICTABLE](#).
- The trapped instruction is not UNDEFINED in the mode in which it is executed, except for the following cases in which an UNDEFINED instruction might cause a Hyp Trap exception:
  - A trapped conditional UNDEFINED instruction that, if it was not trapped, would generate an Undefined Instruction exception, see [Hyp traps on instructions that fail their condition code check on page G1-3505](#).
  - A EL0 mode access to IMPLEMENTATION DEFINED CP15 features in primary CP15 register c9-c11, see [Trapping accesses to lockdown, DMA, and TCM operations on page G1-3508](#).
  - A EL0 mode access to an IMPLEMENTATION DEFINED CP15 register for which there is a generic Hyp trap, see [Generic trapping of accesses to CP15 system control registers on page G1-3513](#).
  - When HCR.TGE is set to 1, any instruction executed in Non-secure User mode that generates an Undefined Instruction exception, see [Undefined Instruction exception, when HCR.TGE is set to 1 on page G1-3452](#).

---

### Note

- These rules mean that, for traps on system control register accesses, unless the specific trap description states otherwise:
  - If the register description in this manual describes the register as not being accessible from User mode in Non-secure state, the implementation of EL2 does not change this behavior. User mode accesses to the register cannot be trapped.
  - If the register description in this manual describes the register as being accessible from User mode in Non-secure state, when accesses to the register are trapped to Hyp mode the trap applies to accesses from both Non-secure EL1 modes and from the Non-secure EL0 mode.
- Traps to Hyp mode never apply in Secure state, regardless of the value of the SCR.NS bit.
- Although a Hyp Trap exception cannot be generated when the PE is in Hyp mode, the HCPTR restricts coprocessor accesses in Hyp mode, as well as in the Non-secure EL1 modes. If the HCPTR settings generate an exception when the PE is in Hyp mode, that exception is taken using the Hyp mode Undefined Instruction vector, not the Hyp Trap vector.
- EL0 mode is a synonym for User mode.

---

Many instructions that can be trapped by a Hyp trap are UNDEFINED in User mode. For these instructions, enabling a Hyp trap on the instruction has no effect on operation in Non-secure User mode. A small number of traps also apply to operations in Non-secure User mode. This means they trap operations at EL0 and at EL1.

## Hyp traps on instructions that fail their condition code check

If the PE executes an instruction that has a Hyp trap set, and that instruction fails its condition code check, unless the specific trap description states otherwise, it is IMPLEMENTATION DEFINED which of the following occurs:

- The instruction generates a Hyp Trap exception.
- The instruction executes as a NOP.

### ———— Note ————

The architecture requires that a Hyp trap on a conditional SMC instruction generates an exception only if the instruction passes its condition code check, see *Trapping use of the SMC instruction* on page G1-3510.

This is consistent with the treatment of conditional undefined instructions, as described in *Conditional execution of undefined instructions* on page G1-3478. Any implementation must be consistent in its handling of instructions that fail their condition code check, meaning that whenever a Hyp trap is set on such an instruction it must either:

- Always generate a Hyp Trap exception.
- Always treat the instruction as a NOP.

This requirement that an implementation is consistent in its handling of instructions that fail their condition code check also means that the IMPLEMENTATION DEFINED part of the requirements of *Conditional execution of undefined instructions* on page G1-3478 must be consistent with the handling of Hyp traps on instructions that fail their condition code check, as Table G1-23 shows:

**Table G1-23 Consistent handling of instructions that fail their condition code check**

Behavior of conditional UNDEFINED instruction <sup>a</sup>	Hyp trap on instruction that fails its condition code check <sup>b</sup>
Executes as a NOP	Executes as a NOP
Generates an Undefined Instruction exception	Generates a Hyp Trap exception

- a. As defined in *Conditional execution of undefined instructions* on page G1-3478. In Non-secure EL1 and ELO modes, applies only if no Hyp trap is set for the instruction, otherwise see the behavior in the other column of the table.
- b. For a trapped instruction executed in a Non-secure EL1 or ELO mode.

## Hyp traps on instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE, but is in a class that has a Hyp trap, the behavior of the instruction when the Hyp trap is enabled is UNPREDICTABLE. The architecture permits such an instruction to generate a Hyp Trap exception, but does not require it to do so.

### ———— Note ————

UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE. This means that setting a Hyp trap on an instruction changes the set of instructions that might be executed in Non-secure state at EL1 or ELO. This affects, indirectly, the permitted behavior of UNPREDICTABLE instructions.

If no instructions are configured to generate Hyp traps, then the attempted execution of an UNPREDICTABLE instruction in a Non-secure EL1 or ELO mode cannot generate a Hyp Trap exception.

## Hyp traps on instructions that are UNDEFINED

Except where explicitly stated in this manual, if an enabled Hyp trap is associated with an instruction that would otherwise be UNDEFINED, attempting to execute that instruction from a Non-secure EL1 or ELO mode generates an Undefined Instruction exception that is taken to EL1, not a Hyp Trap exception.

## Traps of register access instructions

When an attempt to execute an instruction is trapped to Hyp mode, the trap is taken before execution of the instruction. This means that, if the trapped instruction is a register access instruction, before taking the Hyp Trap exception:

- No register access is made.
- No side-effects normally associated with the register access occur.

### G1.16.2 Trapping ID mechanisms

#### ———— Note —————

The PE ID registers that can be accessed from Non-secure state can present a virtualization hole, since system software can use them to determine information about the physical hardware that a hypervisor might want to conceal. However, many uses of virtualization do not require the hypervisor to disguise the identity of the implemented PE.

For a small number of frequently-accessed ID registers, EL2 provides read/write aliases of the registers, accessible only from Hyp mode, or from Secure state. A read of the original ID register from a Non-secure EL1 mode actually returns the value of the read/write alias register. This register substitution is invisible to the software reading the register.

**Table G1-24 ID register substitution by EL2 using AArch32**

Physical ID register	RW alias register
MIDR	VPIDR
MPIDR	VMPIDR

A reset into AArch32 state sets [VPIDR](#) to the [MIDR](#) value, and [VMPIDR](#) to the [MPIDR](#) value.

Reads of [MIDR](#) or [MPIDR](#) from Hyp mode or from Secure state are unchanged by the implementation of EL2, and access the physical registers. This also applies to accesses from Monitor mode with [SCR.NS](#) set to 1.

#### ———— Note —————

A hypervisor often has to virtualize one or both of the [MIDR](#) and [MPIDR](#) because:

- The [MIDR](#) provides information about the implementer, the PE name, and revision information.
- In a multiprocessor implementation, the [MPIDR](#) defines the PE position within a cluster.

EL2 divides the remaining ID registers into a number of groups, and provide a bit for each group in the [HCR](#), to control trapping of accesses to that group of registers. Setting one of these [HCR](#) bits to 1 means that any attempt to read a register in that group from a Non-secure mode other than Hyp mode generates a Hyp Trap exception, unless the register description indicates that the attempted access is UNDEFINED. These traps have no effect on writes to these registers.

#### ———— Note —————

Most but not all of the ID registers are RO registers, and write accesses to these registers behave as described in [Read-only and write-only register encodings](#) on page G3-3695. Each register description identifies whether the register is RO.

Table G1-25 shows the HCR trap bits, and references the subsections that define the registers in each group. Each group description also indicates how the trap is reported to the exception handler.

**Table G1-25 ID register groups for Hyp Trap exceptions**

Trap bit	Register group definition
HCR.TID0	ID group 0, Primary device identification registers
HCR.TID1	ID group 1, Implementation identification registers
HCR.TID2	ID group 2, Cache identification registers
HCR.TID3	ID group 3, Detailed feature identification registers on page G1-3508

### ID group 0, Primary device identification registers

———— **Note** —————

With [MIDR](#) and [MPIDR](#), these registers provide the coarse-grained identification mechanisms that software is likely to access.

The registers that are in ID group 0 for Hyp traps are the [FPSID](#) register and the [JIDR](#).

When an exception is taken because [HCR.TID0](#) is set to 1, the [HSR](#) reports the exception:

- Using EC value 0x05, trapped CP14 access, for a read of [JIDR](#).
- Using EC value 0x08, trapped CP10 access, for a read of [FPSID](#).

If the [HCPTR](#) traps accesses to CP10 and CP11, then for a read of [FPSID](#) that trap has priority over the ID group 0 trap. For more information, see [Trapping accesses to coprocessors on page G1-3511](#).

For more information about the exception reporting, see [Use of the HSR on page G3-3672](#).

### ID group 1, Implementation identification registers

———— **Note** —————

These registers often provide coarse-grained identification mechanisms for implementation-specific features.

The registers that are in ID group 1 for Hyp traps are the [TCMTR](#), [TLBTR](#), [REVIDR](#), and [AIDR](#).

When an exception is taken because [HCR.TID1](#) is set to 1, the [HSR](#) reports the exception as a trapped CP15 access, using the EC value 0x03, see [Use of the HSR on page G3-3672](#).

### ID group 2, Cache identification registers

———— **Note** —————

These are the registers that describe and control the cache implementation.

The registers that are in ID group 2 for Hyp traps are the [CTR](#), [CCSIDR](#), [CLIDR](#), and [CSSELR](#).

When an exception is taken because [HCR.TID2](#) is set to 1, the [HSR](#) reports the exception as a trapped CP15 access, using the EC value 0x03, see [Use of the HSR on page G3-3672](#).

### ID group 3, Detailed feature identification registers

———— **Note** ————

These are the AArch32 CUID registers, that provide detailed information about the features of the PE implementation. In many implementations of virtualization the hypervisor will not trap accesses to registers in this group. The architecture only requires this trap to apply to the registers listed in this section. There is no requirement for the trap to apply to the registers that the CUID identification scheme defines as reserved.

The registers that are in ID group 3 for Hyp traps are the [ID\\_PFR0](#), [ID\\_PFR1](#), [ID\\_DFR0](#), [ID\\_AFR0](#), [ID\\_MMFR0](#), [ID\\_MMFR1](#), [ID\\_MMFR2](#), [ID\\_MMFR3](#), [ID\\_ISAR0](#), [ID\\_ISAR1](#), [ID\\_ISAR2](#), [ID\\_ISAR3](#), [ID\\_ISAR4](#), [ID\\_ISAR5](#), [MVFR0](#), [MVFR1](#), and [MVFR2](#).

When an exception is taken because [HCR.TID3](#) is set to 1, the [HSR](#) reports the exception:

- Using EC value 0x08, trapped CP10 access, for a read of [MVFR0](#), [MVFR1](#), or [MVFR2](#).
- Using EC value 0x03, trapped CP15 access, for a read of any other register in the group.

If the [HCPTR](#) traps accesses to CP10 and CP11, then for reads of [MVFR0](#), [MVFR1](#), and [MVFR2](#), that trap has priority over the ID group 3 trap. For more information, see [Trapping accesses to coprocessors on page G1-3511](#).

For more information about the exception reporting, see [Use of the HSR on page G3-3672](#).

### G1.16.3 Trapping accesses to lockdown, DMA, and TCM operations

The lockdown, DMA, and TCM features of the ARM architecture are IMPLEMENTATION DEFINED. However, the architecture reserves the following CP 15 register encodings for control of these features:

- CRn==c9, opc1=={0-7}, CRm=={c0-c2, c5-c8}, opc2=={0-7}, see [VMSAv8-32 CP15 c9 register summary on page G3-3719](#)
- CRn==c10, opc1=={0-7}, CRm=={c0, c1, c4, c8}, opc2=={0-7}, see [VMSAv8-32 CP15 c10 register summary on page G3-3720](#)
- CRn==c11, opc1=={0-7}, CRm=={c0-c8, c15}, opc2=={0-7}, see [VMSAv8-32 CP15 c11 register summary on page G3-3721](#).

Setting [HCR.TIDCP](#) to 1 means:

- Any attempt to use an MCR or MRC instruction with one of these encodings from a Non-secure EL1 mode generates a Hyp Trap exception.
- On an attempt to use an MCR or MRC instruction with one of these encodings from Non-secure EL0 mode, it is IMPLEMENTATION DEFINED which of the following occurs:
  - The PE takes the Hyp Trap exception.
  - The PE treats the instruction as UNDEFINED, and takes the Undefined Instruction exception to Non-secure Undefined mode.
- Any lockdown fault in the memory system caused by the use of these operations in Non-secure state generates a Data Abort exception that is taken to Hyp mode.

An implementation can include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

When an exception is taken because [HCR.TIDCP](#) is set to 1, the [HSR](#) reports the exception as a trapped CP15 access, using the EC value 0x03, see [Use of the HSR on page G3-3672](#).

———— **Note** ————

- ARM expects the trapping of Non-secure User mode access to these functions to Hyp mode to be unusual, and used only when the hypervisor is virtualizing User mode operation. ARM strongly recommends that, unless the hypervisor must virtualize User mode operation, a Non-secure User mode access to any of these functions generates an Undefined Instruction exception, as it would if the implementation did not include EL2. The PE then takes this exception to Non-secure Undefined mode.

- The trapping of all attempted accesses to these registers from Non-secure EL1 modes overrides the general behavior described in *Hyp traps on instructions that are UNDEFINED* on page G1-3505.

## G1.16.4 Trapping accesses to cache maintenance operations

### ———— Note ————

Virtualizing a uniprocessor system within an MP system, permitting a virtual machine to move between different physical devices, makes cache maintenance by set/way difficult. This is because a set/way operation might be interrupted part way through its operation, and therefore the hypervisor must reproduce the effect of the maintenance on both physical devices

Table G1-26 shows the HCR trap bits that trap cache maintenance operations to the hypervisor. When one of these bits is set to 1, any attempt to access one of the corresponding CP15 c7 operations from a Non-secure EL1 mode generates a Hyp Trap exception.

**Table G1-26 Control of Hyp traps for cache maintenance operations**

Trap bit	Traps	Trapped operations
HCR.TSW	Data cache maintenance by set/way	DCISW, DCCSW, DCCISW
HCR.TPC	Data cache maintenance to point of coherency	DCIMVAC, DCCIMVAC, DCCMVAC
HCR.TPU	Cache maintenance to point of unification	ICIMVAU, ICIALLU, ICIALLUIS, DCCMVAU

For any of these traps, when the exception is taken, the HSR reports the exception as a trapped CP15 access, using the EC value 0x03, see *Use of the HSR* on page G3-3672.

For more information about these operations, see *Cache and branch predictor maintenance operations* on page G3-3743.

## G1.16.5 Trapping accesses to TLB maintenance operations

Setting HCR.TTLB to 1 means that any attempt to access one of the CP15 c8 maintenance operations from a Non-secure EL1 mode generates a Hyp Trap exception. The trapped operations are TLBIALLIS, TLBIMVAIS, TLBIASIDIS, TLBIMVAAIS, DTLBIALL, ITLBIALL, DTLBIMVA, ITLBIMVA, DTLBIASID, ITLBIASID, TLBIMVAA.

When an exception is taken because HCR.TTLB is set to 1, the HSR reports the exception as a trapped CP15 access, using the EC value 0x03, see *Use of the HSR* on page G3-3672.

For more information about these operations, see *The scope of TLB maintenance operations* on page G3-3640.

## G1.16.6 Trapping accesses to the Auxiliary Control Register

### ———— Note ————

The ACTLR is an IMPLEMENTATION DEFINED register that might implement global control bits for the PE. An attempt by a Guest OS to access the ACTLR is a potential virtualization problem. Trapping these accesses to the hypervisor means the hypervisor can react, typically by emulating the required function or signaling a virtualization error.

Setting HCR.TAC to 1 means that any attempt to access the ACTLR from Non-secure state other than from Hyp mode generates a Hyp Trap exception, unless the IMPLEMENTATION DEFINED register description indicates that the attempted access is UNDEFINED.

When an exception is taken because HCR.TAC is set to 1, the HSR reports the exception as a trapped CP15 access, using the EC value 0x03, see *Use of the HSR* on page G3-3672.

## G1.16.7 Trapping accesses to the Performance Monitors Extension

———— **Note** —————

A hypervisor might assign Performance Monitors functionality to a particular Guest OS, or might virtualize performance monitoring. EL2 provides a trap bit that, when set to 1, traps all CP15 accesses to the Performance Monitors to the Hyp Trap exception. A hypervisor might use this as part of a lazy context switch that assigns the Performance Monitors to a particular Guest OS, or might use it as part of a virtualization approach. A second trap bit traps accesses to the **PMCR**. The hypervisor can use this in emulating the Performance Monitors identification bits.

The Performance Monitors Extension is an OPTIONAL architectural extension. The PE accesses the Performance Monitors Extension registers through the CP15 c9 registers with `opc1 == {0-7}`, `CRm == {c12-c15}`, `opc2 == {0-7}`.

In an implementation that includes the Performance Monitors Extension:

- Setting **HDCR.TPM** to 1 traps accesses to the Performance Monitors Extension registers to Hyp mode. When this bit is set to 1, any attempt to access these registers from a Non-secure EL1 or EL0 mode generates a Hyp Trap exception, unless the register description in *Performance Monitors registers on page G4-4170* indicates that the attempted access is UNDEFINED.
- Setting **HDCR.TPMCR** to 1 traps CP15 accesses to the **PMCR** to Hyp mode. The conditions for this trap are identical to those for the trap controlled by **HDCR.TPM**.

For either of these traps, when the exception is taken, the **HSR** reports the exception as a trapped CP15 access, using the EC value 0x03, see *Use of the HSR on page G3-3672*.

## G1.16.8 Trapping use of the SMC instruction

———— **Note** —————

Typically, a hypervisor determines whether a Guest OS can access Secure state directly. If the hypervisor does not permit a particular Guest OS to access Secure state directly, and that Guest OS attempts to change to Secure state, then the hypervisor must either report a virtualization error or emulate the required Secure state operation. To support this, the **HCR** includes a bit that traps use of the SMC instruction to the Hyp Trap exception.

When **HCR.TSC** is set to 1, an attempt to execute an SMC instruction from a Non-secure EL1 mode generates a Hyp Trap exception, regardless of the value of **SCR.SCD**.

———— **Note** —————

When **HCR.TSC** is set to 0, **SCR.SCD** controls whether SMC instructions can be executed from Non-secure state:

- When the value of **SCR.SCD** is 0, the SMC instruction executes normally in Non-secure state.
- When the value of **SCR.SCD** is 1, the SMC instruction is UNDEFINED in Non-secure state.

The **HCR.TSC** trap mechanism traps the attempted execution of a conditional SMC instruction only if the instruction passes its condition code check.

When an exception is taken because **HCR.TSC** is set to 1, the **HSR** reports the exception as a trapped SMC instruction, using the EC value 0x13, see *Use of the HSR on page G3-3672*.

## G1.16.9 Trapping use of the WFI and WFE instructions

### ———— Note ————

An operating system can use the WFI mechanism to signal to the PE that it can suspend operation until it receives an interrupt. In a virtualized system, the hypervisor might use this signal as an indication that it can switch to another Guest OS. Therefore, the **HCR** includes a bit that traps attempted execution of a WFI instruction to the Hyp Trap exception.

Software can use the WFE mechanism to signal to the PE that it can suspend execution during polling of a variable, such as a spinlock. In a virtualized system, WFE might indicate an opportunity for the hypervisor to reschedule. However, WFE generally requires a shorter wait than WFI, and therefore there might be situations where rescheduling on WFE is not appropriate.

For this reason, the **HCR** includes separate bits for trapping WFI and WFE to the Hyp Trap exception.

When **HCR.TWI** is set to 1, and the PE is in a Non-secure mode other than Hyp mode, execution of a WFI instruction generates a Hyp Trap exception if, ignoring the value of the **HCR.TWI** bit, conditions permit the PE to suspend execution. For more information about when a WFI instruction can cause the PE to suspend execution, see [Wait For Interrupt on page G1-3463](#).

When **HCR.TWE** is set to 1, and the PE is in a Non-secure mode other than Hyp mode, execution of a WFE instruction generates a Hyp Trap exception if, ignoring the value of the **HCR.TWE** bit, conditions permit the PE to suspend execution. For more information about when a WFE instruction can cause the PE to suspend execution, see [Wait For Event and Send Event on page G1-3460](#).

For either of these traps, when the exception is taken, the **HSR** reports the exception as a trapped WFI or WFE instruction, using the EC value 0x01, see [Use of the HSR on page G3-3672](#).

## G1.16.10 Trapping accesses to the T32EE configuration registers

Setting **HSTR.TTEE** to 1 means that, when the PE is in a Non-secure mode other than Hyp mode, any access to the T32EE configuration registers **TEECR** and **TEEHBR** that this reference manual does not describe as UNDEFINED, generates a Hyp Trap exception.

When an exception is taken because **HSTR.TTEE** is set to 1, the **HSR** reports the exception as a trapped CP14 access, using the EC value 0x05, see [Use of the HSR on page G3-3672](#).

## G1.16.11 Trapping accesses to coprocessors

### ———— Note ————

- A hypervisor might use the coprocessor access trapping mechanism as part of an implementation of lazy switching of Guest OSs.
- One function of the **CPACR** is as an ID register that identifies what coprocessor functionality is implemented. A hypervisor can trap **CPACR** accesses, to emulate this ID mechanism.

The **HCPTR** provides bits that trap CP10 and CP11 coprocessor operations to Hyp mode. The traps controlled by the **HCPTR** apply regardless of whether the PE is in Debug state.

As described in [Access controls on CP10 and CP11 on page G1-3492](#), the **HCPTR** traps are secondary to the controls provided by the **CPACR** and **NSACR**. Only if those controls permit a Non-secure access to a coprocessor can the **HCPTR** setting trap that access to Hyp mode.

If the **NSACR.cpn** control bit is set to 1, prohibiting Non-secure accesses to coprocessor *n*, then:

- Non-secure accesses to the coprocessor behave as if **HCPTR.TCPn** is set to 1, regardless of the value of that bit.
- Non-secure writes to the corresponding **HCPTR.TCPn** bit are ignored.
- Non-secure reads of **HCPTR.TCPn** return 1, regardless of the actual value of that bit.

In addition, for the [HCPTR](#) traps on coprocessor accesses, and on the use of Advanced SIMD functionality, if a trap bit is set to 1, an attempt to access the trapped functionality from Hyp mode generates an Undefined Instruction exception, that is taken to Hyp mode.

The following subsections give more information about the [HCPTR](#) traps:

- [Trapping of Advanced SIMD functionality.](#)
- [General trapping of coprocessor accesses.](#)
- [Trapping CPACR accesses on page G1-3513.](#)

[Trapping CP14 accesses to trace registers on page G1-3516](#) describes an additional [HCPTR](#) trap.

## Trapping of Advanced SIMD functionality

When the settings in the [CPACR](#) and [NSACR](#) permit Non-secure accesses to Advanced SIMD functionality, and the values of [HCPTR](#).{TCP10, TCP11} are {0, 0}, if the value of [HCPTR](#).TASE is 1, execution of any Advanced SIMD instruction:

- From a Non-secure mode other than Hyp mode generates a Hyp Trap exception.

———— **Note** —————

If the value of [CPACR](#).ASEDIS is 1, the [CPACR](#).ASEDIS setting takes priority. This means any execution of an Advanced SIMD instruction by Non-secure software executing at EL1 or EL0 generates an Undefined Instruction exception, taken to Non-secure Undefined mode, and is not trapped to Hyp mode.

- From Hyp mode generates an Undefined Instruction exception, taken to Hyp mode, with the [HSR](#) holding a syndrome for the instruction.

———— **Note** —————

When the value of [HCPTR](#).TASE is 0, if the [NSACR](#) settings permit Non-secure use of the Advanced SIMD functionality then Hyp mode can access that functionality, regardless of any settings in the [CPACR](#).

When an exception is taken because [HCPTR](#).TASE is set to 1, the [HSR](#) reports the exception as a [HCPTR](#)-trapped coprocessor access, using the EC value 0x07, see [Use of the HSR on page G3-3672](#).

## General trapping of coprocessor accesses

The [HCPTR](#) defines trap bits TCP10 and TCP11, for trapping accesses to coprocessors CP10 and CP11. Setting [HCPTR](#).TCP $n$  to 1 means that an access to coprocessor CP $n$  that is otherwise permitted:

- From a Non-secure mode other than Hyp mode, generates a Hyp Trap exception.

———— **Note** —————

If the [CPACR](#).cp $n$  field does not permit the EL1 or EL0 access, then the [CPACR](#).cp $n$  setting takes priority. This means the access generates an Undefined Instruction exception, taken to Non-secure Undefined mode, and is not trapped to Hyp mode.

- From Hyp mode, generates an Undefined Instruction exception, taken to Hyp mode, with the [HSR](#) holding a syndrome for the instruction.

———— **Note** —————

When [HCPTR](#).TCP $n$  is set to 0, if the [NSACR](#) settings permit Non-secure use of coprocessor CP $n$  then Hyp mode can access that coprocessor, regardless of any settings in the [CPACR](#).

When an exception is taken because an [HCPTR](#).TCP $n$  bit is set to 1, the [HSR](#) reports the exception as a [HCPTR](#)-trapped coprocessor access, using the EC value 0x07, see [Use of the HSR on page G3-3672](#).

## Trapping CPACR accesses

When [HCPTR.TCPAC](#) is set to 1, any access to [CPACR](#) from a Non-secure EL1 mode generates a Hyp Trap exception.

When an exception is taken because [HCPTR.TCPAC](#) is set to 1, the [HSR](#) reports the exception as a trapped CP15 access, using the EC value 0x03, see [Use of the HSR on page G3-3672](#).

### G1.16.12 Trapping writes to virtual memory control registers

#### ———— Note ————

EL2 provides a second stage of address translation, that a hypervisor can use to remap the address map defined by a Guest OS. In addition, a hypervisor can trap attempts by the Guest OS to write to the registers that control the Non-secure memory system. A hypervisor might use this trap as part of its virtualization of memory management.

When the value of [HCR.TVM](#) is 1, any attempt, to write to a Non-secure memory control register from a Non-secure EL1 or EL0 mode, that this reference manual does not describe as UNDEFINED, generates a Hyp Trap exception. This trap applies to accesses to the [SCTLR](#), [TTBR0](#), [TTBR1](#), [TTBCR](#), [DACR](#), [DFSR](#), [IFSR](#), [DFAR](#), [IFAR](#), [ADFSRs](#), [PRRR](#), [NMRR](#), [MAIR0](#), [MAIR1](#), [AMAIR0](#), [AMAIR1](#), and the [CONTEXTIDR](#).

When an exception is taken because [HCR.TVM](#) is set to 1, the [HSR](#) reports the exception:

- As a trapped MCR or MRC CP15 access, using the EC value 0x03, if the access is to a 32-bit register.
- As a trapped MCRR or MRRC CP15 access, using the EC value 0x04, if the access is to a 64-bit register.

For more information about the exception reporting, see [Use of the HSR on page G3-3672](#).

### G1.16.13 Generic trapping of accesses to CP15 system control registers

#### ———— Note ————

- Many of the hypervisor traps described in the section [AArch32 control of traps to the hypervisor on page G1-3503](#) trap specific CP15 system control register operations to Hyp mode. However, because of the large number of possible usage models for virtualization, the traps on specific functions might not meet all possible requirements. Therefore, EL2 also provide a set of generic traps for trapping CP15 accesses to Hyp mode, as described in this subsection.
- ARM expects that trapping of Non-secure User mode accesses to CP15 to Hyp mode will be unusual, and used only when the hypervisor must virtualize User mode operation. ARM recommends that, whenever possible, Non-secure User mode accesses to CP15 behave as they would if the implementation did not include EL2, generating an Undefined Instruction exception taken to Non-secure Undefined mode if the architecture does not support the User mode access.

The [HSTR](#) provides trap bits {T0-T3, T5-T13, T15}, for trapping accesses to each implemented primary CP15 register, {c0-c3, c5-c13, c15}. When the value of a trap bit is 0, it has no effect on accesses to the CP15 registers. When the value of a trap bit is 1, the trap applies as follows:

- In MCR and MRC instructions, CRn specifies the primary CP15 register. The trap applies if the value of CRn corresponds to the trapped primary CP15 register.
- In MCRR and MRRC instructions, CRm specifies the primary CP15 register. The trap applies if the value of CRm corresponds to the trapped primary CP15 register.

For a trapped primary CP15 register:

- Any MCR, MRC, MCRR, or MRRC access from a Non-secure EL1 mode, generates a Hyp Trap exception.
- Any MCR, MRC, MCRR, or MRRC access from Non-secure User mode:
  - Generates a Hyp Trap exception if the access would not be UNDEFINED if the corresponding trap bit was set to 0.
  - Otherwise, generates an Undefined Instruction exception, taken to Non-secure Undefined mode.

If it is IMPLEMENTATION DEFINED whether, when the corresponding trap bit is set to 0, an access from Non-secure User mode is UNDEFINED, then, when the corresponding trap bit is set to 1, it is IMPLEMENTATION DEFINED whether an access from Non-secure User mode generates:

- A Hyp trap exception.
- An Undefined Instruction exception, taken to Non-secure Undefined mode.

This behavior is an exception to the general trapping behavior described in *Hyp traps on instructions that are UNDEFINED* on page G1-3505.

#### Note

- The definition of this trap means that, when **HSTR.Tx** is set to 1, the trap applies to accesses from Non-secure EL1 or EL0 modes:
  - Using an MCR or MRC instruction with CRn set to *x*.
  - Using an MCRR or MRRC instruction with CRm set to *x*.
- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide finer-grained control of control of trapping of IMPLEMENTATION DEFINED features.
- **HSTR** bit[14] is RES0 regardless of whether the implementation includes the Generic Timer, that has its System registers in CP15 c14. The **HSTR** does not provide a trap on accesses to the Generic Timer CP15 registers.

For example, when **HSTR.T7** is set to 1:

- Any 32-bit CP15 access from a Non-secure EL1 mode, using an MRC or MCR instruction with CRn set to *c7*, is trapped to Hyp mode.
- Any 64-bit CP15 access from a Non-secure EL1 mode, using an MRRC or MCRR instructions with CRm set to *c7*, is trapped to Hyp mode.

When an exception is taken because an **HSTR.Tn** bit is set to 1, the **HSR** reports the exception:

- As a trapped MCR or MRC CP15 access, using the EC value 0x03, if the access uses an MCR or MRC instruction.
- As a trapped MCRR or MRRC CP15 access, using the EC value 0x04, if the access uses an MCRR or MRRC instruction.

For more information about the exception reporting, see *Use of the HSR* on page G3-3672.

### G1.16.14 Trapping CP14 accesses to debug registers

Bits in **HDCR** control the trapping of Non-secure CP14 accesses to Hyp mode. When the value of a **HDCR** control bit is 1, and the PE is executing in a Non-secure mode other than Hyp mode and is in Non-debug state, any access to an associated debug register through the CP14 interface generates a Hyp Trap exception.

CP14 register accesses can have side-effects. When a CP14 register access is trapped to Hyp mode, no side-effects occur before the exception is taken, see *Traps of register access instructions* on page G1-3506.

For more information about the reporting of the exceptions see *Use of the HSR* on page G3-3672.

The following sections summarize the **HDCR** control bits, the associated debug registers, and the **HSR** reporting of the Hyp Trap exception:

- *Trapping CP14 accesses to Debug ROM registers.*
- *Trapping CP14 accesses to OS-related debug registers on page G1-3515.*
- *Trapping general CP14 accesses to debug registers on page G1-3515.*
- *Permitted combinations of HDCR.{TDRA, TDOSA, TDA, TDE} bits on page G1-3515.*

#### Trapping CP14 accesses to Debug ROM registers

When the value of **HDCR.TDRA** is 1, if the PE is executing in a Non-secure mode other than Hyp mode, and is in Non-debug state, any CP14 access to **DBGDRAR** or **DBGDSAR** generates a Hyp Trap exception.

If the value of `HDCR.TDE` is 1, or the value of `HDCR.TDA` is 1, the value of `HDCR.TDRA` must be 1, otherwise behavior is UNPREDICTABLE. For more information about `HDCR.TDE`, see [Routing Debug exceptions to Hyp mode on page G1-3454](#).

The `HSR` reports the exception as a trapped MCR or MRC access to CP14, using the EC value `0x05`.

### Trapping CP14 accesses to OS-related debug registers

When the value of `HDCR.TDOSA` is 1, if the PE is executing in a Non-secure mode other than Hyp mode, and is in Non-debug state, any CP14 access to an OS-related debug register generates a Hyp Trap exception.

If the value of `HDCR.TDE` is 1, or the value of `HDCR.TDA` is 1, the value of `HDCR.TDOSA` must be 1, otherwise behavior is UNPREDICTABLE. For more information about `HDCR.TDE`, see [Routing Debug exceptions to Hyp mode on page G1-3454](#).

The OS-related debug registers are:

- `DBGOSLSR`, `DBGOSLAR`, `DBGOSDLR`, and `DBGPRCR`.
- Any IMPLEMENTATION DEFINED integration registers.
- Any IMPLEMENTATION DEFINED register with similar functionality, that the implementation specifies is trapped by `HDCR.TDOSA`.

Depending on the instruction used for the attempted register access, the `HSR` reports the exception:

- For an access to a 32-bit CP14 register, as a trapped MCR or MRC access to CP14, using the EC value `0x05`.
- For an access to a 64-bit register, as a trapped MRRC access to CP14, using the EC value `0x0C`.

### Trapping general CP14 accesses to debug registers

When the value of `HDCR.TDA` is 1, if the PE is executing in a Non-secure mode other than Hyp mode, and is in Non-debug state, any CP14 access to a Debug register generates a Hyp Trap exception, except for:

- Any access that this reference manual describes as UNPREDICTABLE or as causing an Undefined Instruction exception. Accesses described as UNPREDICTABLE can generate a Hyp Trap exception, but the architecture does not require them to do so, see UNPREDICTABLE.
- Any access to `DBGDRAR` or `DBGDSAR`. For more information about trapping accesses to these registers see [Trapping CP14 accesses to Debug ROM registers on page G1-3514](#).
- Any access to an OS-related debug register. For a list of these registers, and more information about trapping accesses to them, see [Trapping CP14 accesses to OS-related debug registers](#).

Accesses trapped to Hyp mode when the value of `HDCR.TDA` is 1 include STC accesses to `DBGDTRTXint`, and LDC accesses to `DBGDTRTXint`.

When the value of `HDCR.TDA` is 1, the value of `HDCR.{TDRA, TDOSA}` must be {1, 1}, otherwise behavior is UNPREDICTABLE.

If the value of `HDCR.TDE` is the value of 1, the value of `HDCR.TDA` must be 1, otherwise behavior is UNPREDICTABLE. For more information about `HDCR.TDE`, see [Routing Debug exceptions to Hyp mode on page G1-3454](#).

Depending on the instruction used for the attempted register access, the `HSR` reports the exception:

- As a trapped MCR or MRC access to CP14, using the EC value `0x05`.
- As a trapped LDC or STC access to CP14, using the EC value `0x06`.

### Permitted combinations of HDCR.{TDRA, TDOSA, TDA, TDE} bits

The permitted values of the `HDCR.{TDRA, TDOSA, TDA, TDE}` bits are `0b0000`, `0b0100`, `0b1000`, `0b1100`, `0b1110`, and `0b1111`. When the value of `HDCR.TDE` is 1, each of the `HDCR.{TDRA, TDOSA, TDA}` bits is treated as 1 for all purposes other than reading the `HDCR` register.

### G1.16.15 Trapping CP14 accesses to trace registers

When the value of [HCPTR.TTA](#) is 1, any access to a CP14 Trace register through the CP14 interface, except for accesses that the appropriate Trace Architecture Specification describes as UNPREDICTABLE or as causing an Undefined Instruction exception:

- If made from a Non-secure EL1 or EL0 mode, generates a Hyp Trap exception.
- If made from Hyp mode, generates an Undefined Instruction exception, taken to Hyp mode, with the [HSR](#) holding a syndrome for the instruction.

———— **Note** —————

Accesses described as UNPREDICTABLE can generate a Hyp Trap or Undefined Instruction exception, but the architecture does not require them to do so. See [UNPREDICTABLE](#).

CP14 register accesses can have side-effects. When a CP14 register access is trapped to Hyp mode, or generates an Undefined Instruction exception, because of the value of [HCPTR.TTA](#), no side-effects occur before the exception is taken, see [Traps of register access instructions on page G1-3506](#).

When the PE is in Debug state, these register accesses do not generate Hyp Trap exceptions, regardless of the value of [HCPTR.TTA](#).

[Trapping accesses to coprocessors on page G1-3511](#) describes other traps controlled by [HCPTR](#).

When a Hyp Trap exception is generated because the value of [HCPTR.TTA](#) is 1, the [HSR](#) reports the exception as a trapped MCR or MRC access to CP14, using the EC value 0x05. For more information see [Use of the HSR on page G3-3672](#).

## G1.16.16 Summary of trap controls

Table G1-27 summarizes the hypervisor trap controls, and the associated trap bits. To provide a single summary of all the controls that can cause entry to Hyp mode, it also includes the exception routing controls described in *Routing general exceptions to EL2* on page G1-3452 and *Routing Debug exceptions to Hyp mode* on page G1-3454.

**Table G1-27 Summary of Hyp trap controls**

Trap description	Controlled by
<i>Trapping ID mechanisms</i> on page G1-3506	HCR.{TID0, TID1, TID2, TID3}
<i>Trapping accesses to lockdown, DMA, and TCM operations</i> on page G1-3508	HCR.TIDCP

# Chapter G2

## The AArch32 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

- *About the memory system architecture* on page G2-3520.
- *Address space* on page G2-3521.
- *Mixed-endian support* on page G2-3522.
- *Cache support* on page G2-3524.
- *ARMv8 CP15 register support for IMPLEMENTATION DEFINED features* on page G2-3545.
- *External aborts* on page G2-3546.
- *Memory barrier instructions* on page G2-3548.
- *Pseudocode details of general memory system instructions* on page G2-3549.

## G2.1 About the memory system architecture

The ARM architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see [Memory hierarchy on page E2-2337](#).

### G2.1.1 Form of the memory system architecture

The ARMv8 A-profile architecture includes a *Virtual Memory System Architecture* (VMSA), described in [Chapter G3 The AArch32 Virtual Memory System Architecture](#).

### G2.1.2 Memory attributes

[Memory types and attributes on page E2-2357](#) describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

[Table G2-1](#) shows the memory attributes that are visible at the system level.

**Table G2-1 Memory attribute summary**

Memory type	Shareability	Cacheability
Device <sup>a</sup>	Outer Shareable	Non-cacheable.
Normal	One of: <ul style="list-style-type: none"><li>• Non-shareable.</li><li>• Inner Shareable.</li><li>• Outer Shareable.</li></ul>	One of: <ul style="list-style-type: none"><li>• Non-cacheable<sup>b</sup>.</li><li>• Write-Through Cacheable.</li><li>• Write-Back Cacheable.</li></ul>

a. Takes additional attributes, see [Device memory on page E2-2360](#).

b. See also [Cacheability, cache allocation hints, and cache transient hints on page G2-3526](#).

For more information on cacheability and shareability see [The cacheability and shareability memory attributes on page E2-2338](#), [Non-shareable Normal memory on page E2-2359](#), and [Caches and memory hierarchy on page E2-2337](#).

## G2.2 Address space

The ARMv8 architecture is designed to support a wide range of applications with different memory requirements. It supports a range of *physical address* (PA) sizes, and provides associated control and identification mechanisms. For more information, see [About VMSAv8-32 on page G3-3562](#).

### G2.2.1 Address space overflow or underflow

When a PE performs a normal, sequential execution of instructions, it calculates:

$$(\text{address\_of\_current\_instruction}) + (\text{size\_of\_executed\_instruction})$$

This calculation is performed after each instruction to determine which instruction to execute next.

#### Instruction address space overflow

If the address calculation performed after executing an A32 or T32 instruction overflows `0xFFFF FFFF`, the program counter becomes UNKNOWN.

———— **Note** —————

Address tags are not propagated to the program counter, so the tag does not affect the address calculation.

Where an instruction accesses a sequential set of bytes that crosses the `0xFFFF_FFFF` boundary the virtual address accessed for the bytes above this boundary is UNKNOWN.

#### Data address space overflow and underflow

Address calculations associated with data access can cause a data access to be performed at:

- An incremented address that crosses the `0xFFFF FFFF` boundary.
- A decremented address that crosses the `0x0` boundary.

In both cases the computed address is UNKNOWN.

## G2.3 Mixed-endian support

Table G2-2 shows the endianness of explicit data accesses and translation table walks.

Table G2-2 Endianness support

Exception level	Explicit data accesses	Stage 1 translation table walks	Stage 2 translation table walks
EL0	CPSR.E	SCTLR(S/NS).EE	HSCTLR.EE
EL1	CPSR.E	SCTLR(S/NS).EE	HSCTLR.EE
EL2	CPSR.E	HSCTLR.EE	N/A
EL3	CPSR.E	SCTLR(S).EE	N/A

ARMv8 provides the following options for endianness support:

- All Exception levels support mixed-endianness:
  - [SCTLR\(S/NS\).EE](#), [HSCTLR.EE](#), and [CPSR.E](#) are R/W.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
  - [SCTLR\(S/NS\).EE](#) and [HSCTLR.EE](#) are RES0. [CPSR.E](#) is R/W when in EL0 and RES0 when in EL1, EL2, or EL3. [SPSR.E](#) is also RES0 when not returning to EL0.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
  - [SCTLR\(S/NS\).EE](#) and [HSCTLR.EE](#) are RES1. [CPSR.E](#) is R/W when in EL0 and RES1 when in EL1, EL2, or EL3. [SPSR.E](#) is also RES1 when not returning to EL0.
- All Exception levels support only little-endianness:
  - [SCTLR\(S/NS\).EE](#) and [HSCTLR.EE](#) are RES0, and [CPSR.E](#) is RES0. [SPSR.E](#) is RES0.
- All Exception levels support only big-endianness:
  - [SCTLR\(S/NS\).EE](#) and [HSCTLR.EE](#) are RES1, and [CPSR.E](#) is RES1. [SPSR.E](#) is RES1.

### Note

- When using AArch32, ARM deprecates [CPSR.E](#) having a different value from the equivalent System control register EE bit when in EL1, EL2 or EL3. The use of the SETEND instruction is also deprecated.
- If the higher Exception levels are using AArch64, the corresponding registers are:
  - [SCTLR\\_EL1](#) for [SCTLR\(NS\)](#).
  - [SCTLR\\_EL2](#) for [HSCTLR](#).
  - [SCTLR\\_EL3](#) for [SCTLR\(S\)](#).

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by [CPSR.E](#). For exception returns to AArch32 state, [CPSR.E](#) is copied from [SPSR\\_ELx.E](#). If the target Exception level supports only little-endian accesses, [SPSR\\_ELx.E](#) is RES0. If the target Exception level supports only big-endian accesses, [SPSR\\_ELx.E](#) is RES1.

The `BigEndian()` function determines whether the current Exception level and execution state is using big-endian data:

```
// BigEndian()
// =====

boolean BigEndian()
    boolean bigend;
    if UsingAArch32() then
        bigend = (PSTATE.E != '0');
    elsif PSTATE.EL == EL0 then
```

```
        bigend = (SCTLR_EL1.E0E != '0');  
else  
        bigend = (SCTLR[].EE != '0');  
return bigend;
```

## G2.4 Cache support

Cache support includes:

- Cache identification. See [Cache identification on page G2-3525](#).
- Write-through and Write-back attributes, and cache allocation hints and cache transient hints. See [Cacheability, cache allocation hints, and cache transient hints on page G2-3526](#).
- Caches and reset. See [Behavior of caches at reset on page G2-3526](#).
- Enabling and disabling caches. See [Cache enabling and disabling on page G2-3527](#).
- Cache maintenance. See [Cache maintenance instructions on page G2-3534](#).

Additional information relating to caches is provided in the following subsections:

- [The ARMv8 cache maintenance functionality on page G2-3529](#).
- [Branch predictors on page G2-3532](#).
- [Cache lockdown on page G2-3542](#).
- [System level caches on page G2-3543](#).

See also [Chapter G3 The AArch32 Virtual Memory System Architecture](#).

### ———— Note —————

- Branch predictors typically use a form of cache to hold branch target data. Therefore, they are included in this section.
- In the instruction mnemonics, MVA is a synonym for VA.

### G2.4.1 General behavior of the caches

When a memory location is marked with a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
  - A particular implementation.
  - Some memory attributes.
- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.
- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

---

**Note**

---

For more information, see [The interaction of cache lockdown with cache maintenance instructions on page G2-3542](#).

---

- If a memory location both has permissions that mean it can be accessed, either by reads or by writes, for the translation scheme at either the current Exception level or at a higher Exception level, and is marked as Cacheable for that translation regime, then there is no mechanism that can guarantee that the memory location cannot be allocated to an enabled cache at any time.  
Any application must assume that any memory location with such access permissions and cacheability attributes can be allocated to any enabled cache at any time.
- If the cache is disabled, it is guaranteed that no new allocation of memory locations into the cache occurs.
- If the cache is enabled, it is guaranteed that no memory location that does not have a Cacheable attribute is allocated into the cache.
- If the cache is enabled, it is guaranteed that no memory location is allocated to the cache if the access permissions for that location are such that the location cannot be accessed by reads and cannot be accessed by writes in both:
  - The translation regime at the current Exception level.
  - The translation regime at a higher Exception level.
- For data accesses, any memory location that is marked as Normal Shareable is guaranteed to be coherent with all masters in that shareability domain.
- Any memory location is not guaranteed to remain incoherent with the rest of memory.
- The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the *Cache Write-back Granule*. In some implementations the CTR identifies the Cache Write-back Granule, see [CTR, Cache Type Register on page G4-3815](#).
- The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer, if it was previously visible to that observer.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to its size.

In the following situations it is UNPREDICTABLE whether the location is returned from cache or from memory:

- The location is not marked as Cacheable but is contained in the cache. This situation can occur if a location is marked as Non-cacheable after it has been allocated into the cache.
- The location is marked as Cacheable and might be contained in the cache, but the cache is disabled.

## G2.4.2 Cache identification

The ARMv8 cache identification consists of a set of registers that describe the implemented caches that are under the control of the PE:

- A single Cache Type Register defines:
  - The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
  - The minimum line length of any of the data or unified caches, affected by the data cache maintenance instructions.
  - The cache indexing and tagging policy of the Level 1 instruction cache.

For more information, see [CTR, Cache Type Register on page G4-3815](#).

- A single Cache Level ID Register defines:
  - The type of cache implemented at each cache level, up to the maximum of seven levels.

- The Level of Coherence and the Level of Unification for the caches. See *Terms used in describing the maintenance instructions* on page G2-3529 for a definition of these terms.

For more information, see *CLIDR, Cache Level ID Register* on page G4-3801.

- A single Cache Size Selection Register selects the cache level and cache type of the current Cache Size Identification Register, see *CSSELR, Cache Size Selection Register* on page G4-3813.
- For each implemented cache, across all the levels of caching, a Cache Size Identification Register defines:
  - Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.
  - The number of sets, associativity and line length of the cache. See *Terms used in describing the maintenance instructions* on page G2-3529 for a definition of these terms.

For more information, see *CCSIDR, Current Cache Size ID Register* on page G4-3799.

### G2.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and can be defined independently for Inner and Outer cache locations.

As described in *Memory types and attributes* on page E2-2357, the memory attributes include a cacheability attribute that is one of:

- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

Cacheability attributes other than Non-cacheable can be complemented by a *cache allocation hint*. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. A *cache transient hint* provides a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. These hints are used to limit cache pollution to a part of a cache, such as to a subset of ways.

The following cache allocation hints can be used in ARMv8:

- Read-Allocate, Transient Read-Allocate, or no Read-Allocate.
- Write-Allocate, Transient Write-Allocate, or no Write-Allocate.

#### ———— **Note** —————

A Cacheable location with both no Read-Allocate and no Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, no Read-Allocate, no Write-Allocate.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

### G2.4.4 Behavior of caches at reset

In ARMv8:

- All caches are disabled at reset.
- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before it is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.
- If an implementation permits cache hits when the cache is disabled the cache initialization routine must:
  - Provide a mechanism to ensure the correct initialization of the caches.
  - Be documented clearly as part of the documentation of the device.

In particular, if an implementation permits cache hits when the cache is disabled and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.

- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 cache maintenance instructions.

When it is enabled, the state of a cache is UNPREDICTABLE if the appropriate initialization routine has not been performed.

Similar rules apply to:

- Branch predictor behavior, see *Behavior of the branch predictors at reset* on page G2-3534.
- TLB behavior, see *TLB behavior at reset* on page G3-3631.

## G2.4.5 Cache enabling and disabling

When a data cache or unified cache is disabled for a translation regime, as determined by **SCTLR.C** or **HSCTLR.C**, data accesses and translation table walks from that translation regime to all Normal memory types behave as Non-cacheable for all levels of data caches and unified caches.

For the EL1&0 translation regime:

- When **SCTLR.C** == 0, this makes all stage 1 translations for data accesses to Normal memory Non-cacheable. It also makes all accesses to the EL1&0 stage 1 translation tables Non-cacheable.
- When **HCR2.CD** == 1, this makes all stage 2 translations for data accesses to Normal memory Non-cacheable. It also makes all accesses to the EL1&0 stage 2 translation tables Non-cacheable.

### ———— Note ————

- The stage 1 and stage 2 cacheability attributes are combined as described in *Combining the cacheability attribute* on page G3-3628.
- The **SCTLR.C** bit has no effect on the EL2 and EL3 translation regimes.
- The **HCR2.CD** bit affects only stage 2 of the Non-secure EL1&0 translation regime.

- If **HCR2.CD** is set to 1, then stage 1 EL1&0 translation regime is cacheable regardless of the value of **SCTLR.C**.

For the EL2 translation regime:

- When the value of the **HSCTLR.C** bit is 0, all data accesses to Normal memory using the EL2 translation regime are Non-cacheable. This means all accesses made by the EL2 translation table walks are Non-cacheable.

### ———— Note ————

The **HSCTLR.C** bit has no effect on the EL1&0 and EL3 translation regimes.

For the EL3 translation regime:

- When the value of the **SCTLR.C** bit is 0, all data accesses to Normal memory using the EL3 translation regime are Non-cacheable. This means all accessed made by the EL3 translation table walks are Non-cacheable.

### ———— Note ————

The **SCTLR.C** bit has no effect on the EL1&0 and EL2 translation regimes.

The effect of the **SCTLR.C** or **HSCTLR.C** and **HCR2.CD** bits is reflected in the result of the address translation operations in the PAR.

Disabling the instruction cache for a translation regime, as determined by the [SCTLR.I](#) or [HSCTLR.I](#), makes instruction accesses to all Normal memory types behave as Non-cacheable for all levels of instruction or unified cache.

For the EL1&0 translation regime:

- When [SCTLR.I](#) == 0, all instruction accesses to Normal memory are made Non-cacheable at the first stage of translation.
- When [HCR2.ID](#) == 1, all instruction accesses to Normal memory are made Non-cacheable at the second stage of translation.

———— **Note** —————

- The stage 1 and stage 2 cacheability attributes are combined as described in [Combining the cacheability attribute on page G3-3628](#).
- The [SCTLR.I](#) bit has no effect on the EL2 and EL3 translation regimes.
- The [HCR2.ID](#) bit affects only stage 2 of the Non-secure EL1&0 translation regime.

- If [HCR2.DC](#) is set to 1, then the Non-secure stage 1 EL1&0 translation regime is cacheable regardless of the value of [SCTLR.I](#).

For the EL2 translation regime:

- When the value of the [HSCTLR.I](#) bit is 0, all instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

———— **Note** —————

The [HSCTLR.I](#) bit has no effect on the EL1&0 and EL3 translation regimes.

For the EL3 translation regime:

- When the value of the [SCTLR.I](#) bit is 0, all instruction accesses to Normal memory using the EL3 translation regime are Non-cacheable.

———— **Note** —————

The [SCTLR.I](#) bit has no effect on the EL1&0 and EL2 translation regimes

In addition, for the Secure EL1, EL2, and EL3 translation regimes, when the value of [SCTLR.M](#) or [HSCTLR.M](#) is 0, indicating that the stage 1 translations are disabled for that translation regime, [SCTLR.I](#) or [HSCTLR.I](#) has the following effect:

- If [SCTLR.I](#) == 0 or [HSCTLR.I](#) == 0, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If [SCTLR.I](#) == 1 or [HSCTLR.I](#) == 0, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Write-Through, Outer Write-Through.

For the Non-secure EL1 translation regime, when the value of [SCTLR.M](#) is 0, indicating that the stage 1 translations are disabled for that translation regime, and [HCR\\_EL2.DC](#) == 0, the [SCTLR.I](#) bit has the following effect:

- If [SCTLR.I](#) == 0 or [HSCTLR.I](#) == 0, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If [SCTLR.I](#) == 1 or [HSCTLR.I](#) == 1, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Write-Through, Outer Write-Through.

———— **Note** —————

This means that the architecturally required effect of [SCTLR.I](#) or [HSCTLR.I](#) is limited to its effect on caching instruction accesses in unified caches.

## G2.4.6 The ARMv8 cache maintenance functionality

The following sections give general information about the ARMv8 cache maintenance functionality:

- [Terms used in describing the maintenance instructions.](#)
- [The ARMv8 abstraction of the cache hierarchy on page G2-3532.](#)

The following sections describe cache maintenance instructions for ARMv8:

- [Instruction cache maintenance instructions \(IC\\*\) on page G2-3535.](#)
- [Data cache maintenance instructions \(DC\\*\) on page G2-3535.](#)

### Terms used in describing the maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instructions can be defined:

- By the address of the memory location to be maintained, referred to as operating *by VA*.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating *by set/way*.

In addition, for instruction caches and branch predictors, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- [Terminology for cache maintenance instruction operating by virtual address, VA.](#)
- [Terminology for cache maintenance instructions operating by set/way on page G2-3530.](#)
- [Terminology for Clean, Invalidate, and Clean and Invalidate instructions on page G2-3530.](#)

#### **Terminology for cache maintenance instruction operating by virtual address, VA**

In a VMSA implementation, the addresses used by the PE are VAs. When all applicable stages of translation are disabled, the VA is identical to the PA.

#### ———— **Note** —————

For more information about memory system behavior when MMUs are disabled, see [The effects of disabling address translation stages on VMSAv8-32 behavior on page G3-3569.](#)

For the cache maintenance instruction, any instruction described as operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current system *Address Space Identifier (ASID)*.
- The current Security state.
- Whether the instruction was performed from Hyp mode, or from Non-secure EL1 state.
- For an instruction executed from a Non-secure EL1 state, the *Virtual Machine Identifier, VMID*.

For a data or unified cache operation by VA, the operation cannot generate a Data Abort exception for a Domain fault or a Permission fault, except for the Permission fault cases described in:

- [Effects of virtualization and security on the cache maintenance instructions on page G2-3537.](#)
- [Stage 2 fault on a stage 1 translation table walk on page G3-3654.](#)

For an instruction cache operation by VA:

- It is IMPLEMENTATION DEFINED whether the operation can generate a Data Abort exception for a Translation fault or an Access flag fault.
- The operation cannot generate a Data Abort exception for a Domain fault or a Permission fault, except for the Permission fault case described in [Stage 2 fault on a stage 1 translation table walk on page G3-3654.](#)

For more information about these faults, see [MMU faults in AArch32 state on page G3-3655.](#)

### **Terminology for cache maintenance instructions operating by set/way**

Cache maintenance instructions that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

- Level** The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED and can be determined from the Cache Level ID register. See [CLIDR, Cache Level ID Register on page G4-3801](#).  
In the ARM architecture, the lower numbered levels are those closest to the PE. See [Memory hierarchy on page E2-2337](#).
- Set** Each level of a cache is split up into a number of *sets*. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.  
In the ARM architecture, sets are numbered from 0.
- Way** The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The *way* number specifies one of these locations.  
In the ARM architecture, ways are numbered from 0.

#### **Note**

Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, ARM expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

### **Terminology for Clean, Invalidate, and Clean and Invalidate instructions**

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.
2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or *stale*, copy of the memory location that has been updated.

The *Clean* and *Invalidate* instructions address these two issues. The definitions of these instructions are:

- Clean** A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the point of unification.  
The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the shareability domain of that memory location.
- Invalidate** A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.  
If the address of an entry on which the invalidate instruction operates does not have a Normal Cacheable attribute, or if the cache is disabled, then an invalidate instruction also ensures that this address is not present in the cache.

---

**Note**

---

Entries for addresses with a Normal Cacheable attribute can be allocated to an enabled cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in an enabled cache.

---

### Clean and Invalidate

A cache *clean and invalidate* instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the point of unification for each location held in the cache.
- For instruction operating by VA, two conceptual points are defined:

#### Point of coherency (PoC)

For a particular VA, the PoC is the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. In many cases, this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherence between memory system agents.

#### Point of unification (PoU)

The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the point of unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

The PoU for an Inner Shareable shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

The following fields in the [CLIDR](#) relate to these conceptual points:

#### LoC, Level of coherence

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

- A clean to the point of coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is  $0x0$ , this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the point of coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the point of coherency.

#### LoUU, Level of unification, uniprocessor

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the PE. As with LoC, the LoUU value is a cache level. If the LoUU field value is  $0x0$ , this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the point of unification.

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the point of unification.

### LoUIS, Level of unification, Inner Shareable

In any implementation:

- This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is 0x0, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the point of unification.

For more information, see [CLIDR, Cache Level ID Register on page G4-3801](#).

## The ARMv8 abstraction of the cache hierarchy

The following subsections describe the ARMv8 abstraction of the cache hierarchy:

- [Cache maintenance instructions that operate by address](#).
- [Cache maintenance instructions that operate by set/way](#).

### Cache maintenance instructions that operate by address

The address-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being either:

- Performed to the point of coherency.
- Performed to the point of unification.

See [Terms used in describing the maintenance instructions on page G2-3529](#) for definitions of point of coherency and point of unification, and more information about possible meanings of VA.

[Cache maintenance instructions on page G2-3534](#) lists the address-based maintenance instructions.

The **CTR** holds minimum line length values for:

- The instruction caches.
- The data and unified caches.

These values support efficient invalidation of a range of addresses, because this value is the most efficient address stride to use to apply a sequence of address-based maintenance instructions to a range of addresses.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the **CTR** defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

### Cache maintenance instructions that operate by set/way

[Cache maintenance instructions on page G2-3534](#) lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.

## G2.4.7 Branch predictors

In AArch32 state it is IMPLEMENTATION DEFINED whether branch prediction is architecturally visible. This means that under some circumstances software must perform branch predictor maintenance to avoid incorrect execution caused by out-of-date entries in the branch predictor. For example, to ensure correct operation it might be necessary to invalidate branch predictor entries on a change to instruction memory, or a change of instruction address mapping. For more information, see [Requirements for branch predictor maintenance operations on page G2-3533](#).

The following branch predictor instructions are part of the AArch32 architecture:

- **BPIMVA:**
  - This instruction invalidates the branch predictor based on a branch address.
- **BPIALLIS:**
  - This instruction invalidates all branch predictors. It operates on all PEs in the Inner Shareable domain of the PE that performs the operation.
- **BPIALL:**
  - This instruction invalidates all branch predictors.

An invalidate all operation on the branch predictor ensures that any location held in the branch predictor has no functional effect on execution. An invalidate branch predictor by VA instruction operates on the address of the branch instruction, but can affect other branch predictor entries.

---

**Note**

---

The architecture does not make visible the range of addresses in a branch predictor to which the invalidate operation applies. This means the address used in the invalidate by VA operation must be the address of the branch to be invalidated.

---

If branch prediction is architecturally visible, an instruction cache invalidate all operation also invalidates all branch predictors.

## Requirements for branch predictor maintenance operations

If, for a given translation regime and a given ASID and VMID as appropriate, the instructions at any virtual address change, then branch predictor maintenance operations must be performed to invalidate entries in the branch predictor, to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

- Enabling or disabling the MMU.
- Writing new mappings to the translation tables.
- Any change to the **TTBR0**, **TTBR1** or **TTBCR** registers, unless accompanied by a change to the ContextID, or a change to the VMID.
- Changes to the **VTTBR** or **VTCTCR** registers, unless accompanied by a change to the VMID.

---

**Note**

---

Invalidation is not required if the changes to the translations are such that the instructions associated with the non-faulting translations of a virtual address, for a given translation regime and a given ASID and VMID, as appropriate, remain unchanged throughout the sequence of changes to the translations. Examples of translation changes to which this applies are:

- Changing a valid translation to a translation that generates a MMU fault.
  - Changing a translation that generates a MMU fault to a valid translation.
- 

Failure to invalidate entries might give UNPREDICTABLE results, caused by the execution of old branches. For more information, see [Ordering of cache and branch predictor maintenance instructions on page G2-3539](#).

---

**Note**

---

- In ARMv8, there is no requirement to use the branch predictor maintenance operations to invalidate the branch predictor after:
    - Changing the ContextID or VMID.
    - A cache operation that is identified as also flushing the branch predictors, see [Cache maintenance instructions on page G2-3534](#).
-

[Cache maintenance operations, functional group on page G3-3743](#) shows the branch predictor maintenance operations in a VMSA implementation.

### Behavior of the branch predictors at reset

In ARMv8:

- If branch predictors are not architecturally invisible the branch prediction logic is disabled at reset.
- An implementation can require the use of a specific branch predictor initialization routine to invalidate the branch predictor storage array before it is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, but the routine must be documented clearly as part of the documentation of the device.
- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 branch predictor maintenance operations.

When it is enabled, the state of the branch predictor logic is UNPREDICTABLE if the appropriate initialization routine has not been performed.

Similar rules apply:

- To cache behavior, see [Behavior of caches at reset on page G2-3526](#).
- To TLB behavior, see [TLB behavior at reset on page G3-3631](#).

## G2.4.8 Cache maintenance instructions

The instruction and data cache maintenance instructions have the same functionality in AArch32 state and in AArch64 state. [Table G2-3](#) shows these system instructions. Instructions that take an argument include Rt in the instruction description.

### ————— Note —————

- In [Table G2-3](#) the point of unification is the point of unification of the PE executing the cache maintenance instruction.

**Table G2-3 System instructions for cache maintenance**

Register	Instruction	Notes
Instruction cache maintenance instructions		
<a href="#">ICIALLUIS</a>	Invalidate all to point of unification, Inner Shareable	EL1 or higher access
<a href="#">ICIALLU</a>	Invalidate all to point of unification	EL1 or higher access
<a href="#">ICIMVAU, Rt</a>	Invalidate by virtual address to point of unification	When <a href="#">SCTLR.UCI</a> == 1, EL0 access. Otherwise, EL1 or higher access
Data cache maintenance instructions		
<a href="#">DCIMVAC, Rt</a>	Invalidate by virtual address to point of coherency	EL1 or higher access
<a href="#">DCISW, Rt</a>	Invalidate by set/way	EL1 or higher access
<a href="#">DCCMVAC, Rt</a>	Clean by virtual address to point of coherency	When <a href="#">SCTLR.UCI</a> == 1, EL0 access Otherwise EL1 or higher access
<a href="#">DCCSW, Rt</a>	Clean by set/way	EL1 or higher access

Table G2-3 System instructions for cache maintenance (continued)

Register	Instruction	Notes
DCCMVAU, Rt	Clean by virtual address to point of unification	When <code>SCTLR.UCI == 1</code> , EL0 access Otherwise EL1 or higher access
DCCIMVAC, Rt	Clean and invalidate by virtual address to point of coherency	When <code>SCTLR.UCI == 1</code> , EL0 access. Otherwise EL1 or higher access
DCCISW, Rt	Clean and invalidate by set/way	EL1 or higher access

### Instruction cache maintenance instructions (IC\*)

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

All instruction cache maintenance instructions can execute in any order relative to other instruction cache maintenance instructions, data cache maintenance instructions, and loads and stores, unless a DSB is executed between the instructions.

An instruction cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction.

### Data cache maintenance instructions (DC\*)

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Data cache maintenance instructions that take a set/way/level argument take a 32-bit register.

A data or unified cache invalidation by MVA operation performed in a Non-secure EL1 mode must change data in any location for which the stage 2 translation permissions do not permit write access. Where such a permission violation occurs, it is IMPLEMENTATION DEFINED whether:

- A stage 2 Permission fault is generated for the `DCIMVAC` operation.
- The `DCIMVAC` operation is upgraded to `DCCIMVAC`.

`DCIMVAC` and `DCISW` at EL1 is performed by hardware as clean and invalidate, that is `DCCIMVAC` or `DCCISW` if all of the following apply:

- EL2 is implemented.
- `HCR.VM` is set to 1 to enable the second stage of address translation, meaning that execution is in Non-secure state.
- `SCR.NS` is set to 1 or EL3 is not implemented.

#### ————— Note —————

Similarly, `DCIMVAC` and `DCISW` at EL1 must be performed as clean and invalidate, that is `DCCIMVAC` and `DCCISW` at EL1 when EL1 is using AArch32, if all of the following apply:

- EL2 is implemented.
- EL2 is using AArch32 and `HCR.VM` is set to the value of 1, or EL2 is using AArch64 and `HCR_EL2.VM` is set to the value of 1.
- EL3 is using AArch32 and `SCR.NS` is set to the value of 1, or EL3 is using AArch64 and `SCR.NS` is set to the value of 1, or EL3 is not implemented.

If a memory fault that sets FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.

## General requirements for the scope of cache and branch predictor maintenance instructions

The ARMv8 specification of the cache maintenance and branch predictor instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in *General behavior of the caches* on page G2-3524, *Behavior of caches at reset* on page G2-3526, and *Preloading caches* on page E2-2340.

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

As a side-effect of a branch predictor maintenance instruction, any entry in the branch predictor might be invalidated.

### ———— Note —————

ARM recommends that, for best performance, such side-effects are kept to a minimum. ARM strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

## Effects of instructions that operate to the point of coherency

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the point of coherency.

**Table G2-4 PEs affected by Data and Unified cache operations**

Shareability	PEs affected	Effective to
Non-shareable	The PE performing the operation	The point of coherency of the entire system
Inner Shareable	All PEs in the same Inner Shareable shareability domain as the PE performing the operation	The point of coherency of the entire system
Outer Shareable	All PEs in the same Outer Shareable shareability domain as the PE performing the operation	The point of coherency of the entire system

## Effects of instructions that do not operate to the point of coherency

For these instructions, [Table G2-5](#) shows how, for a VA in a Normal or Device memory location, the shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

**Table G2-5 PEs affected by address-based cache maintenance instructions**

Shareability	PEs affected	Effective to
Non-shareable	The PE executing the instruction	The point of unification of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction
Inner Shareable or Outer Shareable	All PEs in the same Inner Shareable shareability domain as the PE executing the instruction	The point of unification of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain as the PE executing the instruction

———— **Note** ————

The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable shareability domain containing the PE executing the instruction.

## Effects of virtualization and security on the cache maintenance instructions

Each Security state has its own physical address space, and therefore cache entries are associated with physical address space. In addition, cache maintenance and branch predictor instructions performed in Non-secure state have to take account of:

- Whether the instruction was performed at EL1 or at EL2.
- For instructions that operate by VA, the current VMID.

[Table G2-6](#) shows the effects of virtualization and security on these maintenance instructions.

**Table G2-6 Effects of virtualization and security on the maintenance instructions**

Cache maintenance instructions	Security state	Targeted entry
Data or unified cache maintenance instructions		
Invalidate, Clean, or Clean and Invalidate by VA: DCIMVAC, DCCMVAC, DCCMVAU, DCCIMVAC	Either	All lines that hold the PA that, in the current security state, is mapped to by the combination of all of: <ul style="list-style-type: none"> <li>• The specified VA.</li> <li>• For an instruction executed at EL1, the current ASID.</li> <li>• For an instruction executed at Non-secure EL1, the current VMID<sup>b</sup>.</li> </ul>
Invalidate, Clean, or Clean and Invalidate by set/way: DCISW, DCCSW, DCCISW	Non- secure	Line specified by set/way provided that the entry comes from the Non-secure PA space.
	Secure	Line specified by set/way regardless of the PA space that the entry has come from.

Instruction cache maintenance instructions

**Table G2-6 Effects of virtualization and security on the maintenance instructions (continued)**

Cache maintenance instructions	Security state	Targeted entry
Invalidate by VA: ICIMVAU	Either	Implementation without the IVIPT Extension <sup>a</sup> :  All Lines that match the specified VA, and, for an instruction executed at EL1, the current ASID, and come from the same VA space as the current security state. For an instruction executed in Non-secure state, lines are invalidated only if they also match the current VMID <sup>b</sup> and security level, EL1 or EL2.
		Implementation with the IVIPT Extension: <sup>a</sup>  All Lines that hold the PA that, in the current security state, is mapped to by the combination of all of: <ul style="list-style-type: none"> <li>The specified VA.</li> <li>For an instruction executed at EL1, the current ASID.</li> <li>For an instruction executed in Non-secure EL1, the current VMID<sup>b</sup>.</li> </ul>
Invalidate All: ICIALLU, ICIALUIS		<ul style="list-style-type: none"> <li>Can invalidate any unlocked entry in the instruction cache.</li> <li>Are required to invalidate any entries relevant to the software component that executed it. The Non-secure and Secure descriptions give more information: <p><b>Non-secure</b></p> An instruction executed at EL1 must operate on all instruction cache lines that contain entries associated with the current virtual machine, meaning any entry with the current VMID<sup>b</sup>.  An instruction executed at EL2 must operate on all instruction cache lines that contain entries that can be accessed from Non-secure state. <p><b>Secure</b></p> The instruction must invalidate all instruction cache lines.</li> </ul>
Branch predictor operations		
Invalidate by VA: BPIMVA	Either	All entries that match the specified VA and the current ASID, and come from the same VA space as the current security state. For an operation performed in Non-secure state, entries are invalidated only if they also match the current VMID <sup>b</sup> and security level, EL1 or EL2.
Invalidate all: BPIALL, BPIALLIS		<ul style="list-style-type: none"> <li>Can invalidate any unlocked entry in the instruction cache.</li> <li>Are required to invalidate any entries relevant to the software component that executed it. The Non-secure and Secure descriptions give more information.</li> </ul>

a. See *IVIPT architecture Extension* on page G3-3646.

b. Dependencies on the VMID apply even when HCR\_EL2.VM is set to 0. However, VTTBR\_EL2.VMID resets to zero, meaning there is a valid VMID from reset.

For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in *The interaction of cache lockdown with cache maintenance instructions* on page G2-3542 applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, Non-secure clean by set/way operations can be upgraded to clean and invalidate by set/way.

- The AArch64 Data Cache Invalidate instructions, **DC IVAC** and **DC ISW**, at EL1 and EL0, and the AArch32 Data Cache Invalidate instructions **DCIMVAC** and **DCISW**, perform a cache clean as well as a cache invalidation if all of the following apply:
  - EL2 is implemented.
  - **HCR.VM** is set.
  - **SCR.NS** is set or EL3 is not implemented.
- When the value of **HCR.FB** is 1, TLB and instruction cache invalidate instructions executed in the Non-secure EL1 Exception level are broadcast across the Inner Shareable domain. When Non-secure EL1 is using AArch32, this applies to the **TLBIMVA**, **TLBIASID**, **TLBIMVAA**, **TLBIMVAL**, **TLBIMVAAL**, and **ICIALLU** instructions. This means the instruction is upgraded to the corresponding Inner Shareable instruction, for example **ICIALLU** is upgraded to **ICIALLUIS**, and **BPIALL** is upgraded to **BPIALLIS**.
- When the value of **HCR.SWIO** is 1, a cache invalidate by set/way instructions executed in the Non-secure EL1 Exception level is upgraded to a clean and invalidate by set/way. When Non-secure EL1 is using AArch64, this means the **DCISW** instruction is upgraded to **DCCISW**.

For more information about the cache maintenance instructions, see [The ARMv8 cache maintenance functionality on page G2-3529](#), [Cache maintenance instructions on page G2-3534](#), and [Chapter G3 The AArch32 Virtual Memory System Architecture](#).

### Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches when the caches are enabled or when they are disabled.

For address-based cache maintenance instructions, the instructions operate on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
  - Is Normal memory or Device memory.
  - Has the Cacheable attribute or the Non-cacheable attribute.
- Any applicable domain control of the address accessed.
- The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

### Ordering of cache and branch predictor maintenance instructions

The following rules describe the effect of the memory order model on the cache and branch predictor maintenance instructions:

- All cache and branch predictor maintenance instructions that do not specify an address execute, relative to each other, in program order.
 

All cache and branch predictor instructions that specify an address:

  - Execute in program order relative to all cache and branch predictor operations that do not specify an address.
  - Execute in program order relative to all cache and branch predictor operations that specify the same address.
  - Can execute in any order relative to cache and branch predictor operations that specify a different address.
- Where a cache maintenance or branch predictor instruction appears in program order before a change to the translation tables, the architecture guarantees that the cache or branch predictor maintenance instruction uses the translations that were visible before the change to the translation tables

- Where a change of the translation tables appears in program order before a cache maintenance or branch predictor instruction, software must execute the sequence outlined in [TLB maintenance operations and the memory order model on page G3-3635](#) before performing the cache or branch predictor maintenance instruction, to ensure that the maintenance operation uses the new translations.
- A DMB instruction causes the effect of all data or unified cache maintenance instructions appearing in program order before the DMB to be visible to all explicit load and store operations appearing in program order after the DMB.  
  
Also, a DMB instruction ensures that the effects of any data or unified cache maintenance operations appearing in program order before the DMB are observable by any observer in the same required shareability domain before any data or unified cache maintenance or explicit memory operations appearing in program order after the DMB are observed by the same observer. Completion of the DMB does not guarantee the visibility of all data to other observers. For example, all data might not be visible to a translation table walk, or to instruction fetches.
- A DSB is required to guarantee the completion of all cache maintenance instruction that appear in program order before the DSB instruction.
- A context synchronization operation is required to guarantee the effects of any branch predictor maintenance operation. This means a context synchronization operation causes the effect of all completed branch predictor maintenance operations appearing in program order before the context synchronization operation to be visible to all instructions after the context synchronization operation.

———— **Note** —————

See [Context synchronization operation](#) in the [Glossary](#) for the definition of this term.

This means that, if a branch instruction appears after an invalidate branch predictor operation and before any context synchronization operation, it is UNPREDICTABLE whether the branch instruction is affected by the invalidate. Software must avoid this ordering of instructions, because it might cause UNPREDICTABLE behavior.

- Any data or unified cache maintenance operation by VA must be executed in program order relative to any explicit load or store on the same PE to an address covered by the VA of the cache instruction if that load or store is to Normal Cacheable memory. The order of memory accesses that result from the cache maintenance instruction, relative to any other memory accesses to Normal Cacheable memory, are subject to the memory ordering rules. For more information, see [Memory ordering on page E2-2350](#).  
  
Any data or unified cache maintenance operation by VA can be executed in any order relative to any explicit load or store on the same PE to an address covered by the VA of the cache operation if that load or store is not to Normal Cacheable memory.
- There is no restriction on the ordering of data or unified cache maintenance operations by VA relative to any explicit load or store on the same PE where the address of the explicit load or store is not covered by the VA of the cache instruction. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.
- There is no restriction on the ordering of a data or unified cache maintenance operation by set/way relative to any explicit load or store on the same PE. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.
- Software must execute a context synchronization operation after the completion of an instruction cache maintenance instruction, to guarantee that the effect of the maintenance instruction is visible to any instruction fetch.

The scope of instruction cache maintenance depends on the type of the instruction cache. For more information see [Instruction caches on page G3-3644](#).

### Example G2-1 Cache cleaning operations for self-modifying code

---

The sequence of cache cleaning operations for a line of self-modifying code on a uniprocessor system is:

```

; Enter this code with <Rx> containing the new 32-bit instruction. Use STRH in the first
; line instead of STR for a 16-bit instruction.
STR    <Rx>, [instruction location]
DCCMVAU [instruction location] ; Clean data cache by MVA to point of unification
DSB    ; Ensure visibility of the data cleaned from the cache
ICIMVAU [instruction location] ; Invalidate instruction cache by MVA to PoU
BPIMVAU [instruction location] ; Invalidate branch predictor by MVA to PoU
DSB    ; Ensure completion of the invalidations
ISB    ; Synchronize fetched instruction stream

```

---

## Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache ARM strongly recommends that software:

- For data or unified cache maintenance, uses the `CTR.DMinLine` value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the `CTR.IMinLine` value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

### Example code for cache maintenance instructions

The cache maintenance instructions by set/way can be used to clean or invalidate, or both, the entirety of one or more levels of cache attached to a processing element. However, unless all processing elements attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

#### ———— Note ————

In multi-processing environments, the cache maintenance instructions that operate by set/way are not broadcast within the shareability domains, and so allocations can occur from other, unmaintained, locations, in caches in other locations. For this reason, the use of cache maintenance instructions that operate by set/way for the maintenance of large buffers of memory is not recommended in the architectural sequence. The expected usage of the cache maintenance instructions that operate by set/way is associated with the cache maintenance instructions associated with the powerdown and powerup of caches, if this is required by the implementation.

---

The following example code for cleaning a data or unified cache to the point of coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the point of coherency.

```

MRC p15, 1, R0, c0, c0, 1 ; Read CLIDR into R0
ANDS R3, R0, #0x07000000
MOV R3, R3, LSR #23 ; Cache level value (naturally aligned)
BEQ Finished
MOV R10, #0
Loop1
ADD R2, R10, R10, LSR #1 ; Work out 3 x cachelevel
MOV R1, R0, LSR R2 ; bottom 3 bits are the Cache type for this level
AND R1, R1, #7 ; get those 3 bits alone
CMP R1, #2
BLT Skip ; no cache or only instruction cache at this level
MCR p15, 2, R10, c0, c0, 0 ; write CSELR from R10
ISB ; ISB to sync the change to the CCSIDR
MRC p15, 1, R1, c0, c0, 0 ; read current CCSIDR to R1
AND R2, R1, #7 ; extract the line length field
ADD R2, R2, #4 ; add 4 for the line length offset (log2 16 bytes)
LDR R4, =0x3FF
ANDS R4, R4, R1, LSR #3 ; R4 is the max number on the way size (right aligned)
CLZ R5, R4 ; R5 is the bit position of the way size increment
MOV R9, R4 ; R9 working copy of the max way size (right aligned)
Loop2
LDR R7, =0x0007FFF

```

```
    ANDS R7, R7, R1, LSR #13 ; R7 is the max number of the index size (right aligned)
Loop3
    ORR R11, R10, R9, LSL R5 ; factor in the way number and cache number into R11
    ORR R11, R11, R7, LSL R2 ; factor in the index number
    MCR p15, 0, R11, c7, c10, 2 ; DCCSW, clean by set/way
    SUBS R7, R7, #1 ; decrement the index
    BGE Loop3
    SUBS R9, R9, #1 ; decrement the way number
    BGE Loop2

Skip
    ADD R10, R10, #2 ; increment the cache number
    CMP R3, R10
    BGT Loop1
    DSB
Finished
```

Similar approaches can be used for all cache maintenance instructions.

## G2.4.9 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

### The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  - Cache clean by set/way, [DCCSW](#).
  - Cache invalidate by set/way, [DCISW](#).
  - Cache clean and invalidate by set/way, [DCISW](#).
  - Instruction cache invalidate all, [ICIALLU](#) and [ICIALUIS](#).

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the fault status code defined for this purpose. See [Data Abort exception on page G1-3483](#).

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, [DCCMVAC](#) and [DCCMVAU](#).
- Cache invalidate by virtual address, [DCIMVAC](#).
- Cache clean and invalidate by virtual address, [DCCIMVAC](#).

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the fault status code defined for this purpose. See [DFSR](#) or [HSR](#).

In an implementation that includes EL2, if [HCR.TIDCP](#) is set to 1, any exception relating to lockdown of an entry associated with Non-secure memory is routed to EL2.

———— **Note** —————

An implementation that uses an abort mechanisms for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.

***Additional cache functions for the implementation of lockdown***

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED space. See [IMPLEMENTATION DEFINED registers, functional group on page G3-3751](#).

## G2.4.10 System level caches

The system level architecture might define further aspects of the software view of caches and the memory model that are not defined by the ARMv8 architecture. These aspects of the system level architecture can affect the requirements for software management of caches and coherency. For example, a system design might introduce additional levels of caching that cannot be managed using the architecturally-defined maintenance instructions. Such caches are referred to as *system caches* and are managed through the use of memory-mapped operations. The ARMv8 architecture does not forbid the presence of system caches that are outside the scope of the architecture, but ARM strongly recommends that such caches are always placed after the point of coherency for all memory locations that might be held in a cache. Placing such system caches after the point of coherency means that coherency management does not require maintenance of these system caches.

ARM also strongly recommends:

- For the maintenance of any such system cache:
  - Physical, rather than virtual, addresses are used for address-based cache maintenance instructions.
  - Any IMPLEMENTATION DEFINED system cache maintenance instruction includes at least the set of maintenance options defined by [Cache maintenance instructions on page G2-3534](#), with the number of levels of system cache operated on by the cache maintenance instructions being IMPLEMENTATION DEFINED.

- Wherever possible, all caches that require maintenance to ensure coherency are included in the caches affected by the architecturally-defined cache maintenance instructions, so that the architecturally-defined software sequences for managing the memory model and coherency are sufficient for managing all caches in the system.

## G2.5 ARMv8 CP15 register support for IMPLEMENTATION DEFINED features

The ARMv8 CP15 registers implementation includes the following support for IMPLEMENTATION DEFINED features of the memory system:

- The TCM Type Register, [TCMTR](#), in CP15 c0, must be implemented. The following conditions apply to this register:
  - If no TCMs are implemented, the [TCMTR](#) indicates zero-size TCMs.
  - If bits[31:29] are 0b100, the format of the rest of the register is IMPLEMENTATION DEFINED. This value indicates that the implementation includes TCMs that do not follow the legacy usage model. Other fields in the register might give more information about the TCMs.
- The CP15 c9 encoding space with  $\langle CRm \rangle = \{0-2, 5-7\}$  is IMPLEMENTATION DEFINED for all values of  $\langle opc2 \rangle$  and  $\langle opc1 \rangle$ . This space is reserved for branch predictor, cache and TCM functionality, for example maintenance, override behaviors and lockdown.

For more information, see [VMSAv8-32 CP15 c9 register summary on page G3-3719](#).

- In a VMSAv8 implementation, part of the CP15 c10 encoding space is IMPLEMENTATION DEFINED and reserved for TLB functionality, see [TLB lockdown on page G3-3631](#).
- The CP15 c11 encoding space with  $\langle CRm \rangle = \{0-8, 15\}$  is IMPLEMENTATION DEFINED for all values of  $\langle opc2 \rangle$  and  $\langle opc1 \rangle$ . This space is reserved for DMA operations to and from the TCMs

For more information, see [VMSAv8-32 CP15 c11 register summary on page G3-3721](#).

## G2.6 External aborts

The ARM architecture defines external aborts as errors that occur in the memory system, other than those that are detected by the MMU or Debug hardware. External aborts include parity errors detected by the caches or other parts of the memory system. For example, an uncorrectable parity or ECC failure on a Level 2 Memory structure might generate an external abort.

An external abort is one of:

- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see [Exception terminology on page G1-3402](#).

The ARM architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous aborts.

In AArch32 state, asynchronous aborts are reported using the Data Abort exception.

Synchronous external aborts are reported using the Data Abort exception. See [Handling exceptions that are taken to an Exception level using AArch32 on page G1-3431](#).

VMSAv8-32 permits external aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous. The reported fault code identifies whether the external abort is synchronous or asynchronous.

It is IMPLEMENTATION DEFINED which external aborts, if any, are supported.

Normally, external aborts are rare. An imprecise asynchronous external abort is likely to be fatal to the process that is running. ARM recommends that implementations make external aborts precise wherever possible.

The following subsections give more information about possible external aborts:

- [External abort on instruction fetch](#).
- [External abort on data read or write](#).
- [Provision for classification of external aborts on page G2-3547](#).
- [Parity error reporting on page G2-3547](#).

The section [Exception reporting in a VMSAv8-32 implementation on page G3-3659](#) describes the reporting of external aborts.

### G2.6.1 External abort on instruction fetch

An external abort on an instruction fetch can be either synchronous or asynchronous. A synchronous external abort on an instruction fetch is taken precisely.

An implementation can report the external abort asynchronously from the instruction that it applies to. In such an implementation these aborts behave essentially as interrupts. The aborts are masked when `CPSR.A` is set to 1, otherwise they are reported using the Data Abort exception.

### G2.6.2 External abort on data read or write

Externally-generated errors during a data read or write can be either synchronous or asynchronous.

An implementation can report the external abort asynchronously from the instruction that generated the access. In such an implementation these aborts behave essentially as interrupts. The aborts are masked when `CPSR.A` is set to 1, otherwise they are reported using the Data Abort exception.

### G2.6.3 Provision for classification of external aborts

For a synchronous external abort taken to a privileged mode other than Hyp mode, an implementation can use the [DFSR.ExT](#) and [IFSR.ExT](#) bits to provide more information about synchronous external aborts:

- [DFSR.ExT](#) provides an IMPLEMENTATION DEFINED classification of synchronous external aborts on data accesses.
- [IFSR.ExT](#) provides an IMPLEMENTATION DEFINED classification of synchronous external aborts on instruction accesses.

For a synchronous external abort taken to Hyp mode, the [HSR.EA](#), ISS[9] bit, provides an IMPLEMENTATION DEFINED classification of external aborts.

For all aborts other than synchronous external aborts these bits return a value of 0.

### G2.6.4 Parity error reporting

The ARM architecture supports the reporting of both synchronous and asynchronous parity errors from the cache systems. It is IMPLEMENTATION DEFINED what parity errors in the cache systems, if any, result in synchronous or asynchronous parity errors.

A fault code is defined for reporting parity errors, see [Exception reporting in a VMSAv8-32 implementation on page G3-3659](#). However when parity error reporting is implemented it is IMPLEMENTATION DEFINED whether a parity error is reported using the assigned fault code, or using another appropriate encoding.

For all purposes other than the fault status encoding, parity errors are treated as external aborts.

## G2.7 Memory barrier instructions

[Memory barriers on page E2-2352](#) describes the memory barrier instructions. This section describes the system level controls of those instructions.

### G2.7.1 EL2 control of the shareability of data barrier instructions executed at EL0 or EL1

In an implementation that includes EL2 and supports shareability limitations on the data barrier instructions, the [HCR.BSU](#) field can upgrade the required shareability of an instruction that is executed at EL0 or EL1 in Non-secure state. [Table G2-7](#) shows the encoding of this field:

**Table G2-7 EL2 control of shareability of barrier instructions executed at EL0 or EL1**

<a href="#">HCR.BSU</a>	Minimum shareability of barrier instructions
00	No effect, shareability is as specified by the instruction
01	Inner Shareable
10	Outer Shareable
11	Full system

For an instruction executed at EL0 or EL1 in Non-secure state, [Table G2-8](#) shows how the [HCR.BSU](#) is combined with the shareability specified by the argument of the DMB or DSB instruction to give the scope of the instruction:

**Table G2-8 Effect of the HCR\_EL2.BSU on barrier instructions executed at Non-secure EL1 or EL1**

Shareability specified by the DMB or DSB argument	<a href="#">HCR.BSU</a>	Resultant shareability
Full system	Any	Full system
	00, 01, or 10	Outer Shareable
Outer Shareable	11, Full system	Full system
	00 or 01	Inner Shareable
Inner Shareable	10, Outer Shareable	Outer Shareable
	11, Full system	Full system
Non-shareable	00, No effect	Non-shareable
	01, Inner Shareable	Inner Shareable
	10, Outer Shareable	Outer Shareable
	11, Full system	Full system

## G2.8 Pseudocode details of general memory system instructions

This section contains the following pseudocode describing general memory operations:

- [Memory data type definitions.](#)
- [Basic memory access on page G2-3550.](#)
- [Aligned memory access on page G2-3550.](#)
- [Unaligned memory access on page G2-3551.](#)
- [Exclusive monitors operations on page G2-3552.](#)
- [Access permission checking on page G2-3554.](#)
- [Abort exceptions on page G2-3555.](#)
- [Memory barriers on page G2-3556.](#)

### G2.8.1 Memory data type definitions

This section describes the memory data type definitions.

The address descriptor type is defined as follows:

```
type AddressDescriptor is (
    FaultRecord    fault,    // fault.type indicates whether the address is valid
    MemoryAttributes memattrs,
    FullAddress    paddress
)
```

The full address type is defined as follows:

```
type FullAddress is (
    bits(48) physicaladdress,
    bit      NS                // '0' = Secure, '1' = Non-secure
)
```

The memory attributes types are defined is as follows:

```
type MemoryAttributes is (
    MemType        type,

    DeviceType    device,    // For Device memory types
    MemAttrHints  inner,    // Inner hints and attributes
    MemAttrHints  outer,    // Outer hints and attributes

    boolean       shareable,
    boolean       outershareable
)
```

The memory type is defined as follows.

```
enumeration MemType {MemType_Normal, MemType_Device};
```

The Device memory types are defined as follows:

```
enumeration DeviceType {DeviceType_GRE, DeviceType_nGRE, DeviceType_nGnRE, DeviceType_nGnRnE};
```

For Normal memory, the inner and outer attributes are defined is as follows:

```
type MemAttrHints is (
    bits(2) attrs, // The possible encodings for each attributes field are as below
    bits(2) hints, // The possible encodings for the hints are below
    boolean transient
)
```

The cacheability attributes are defined as follows:

```
constant bits(2) MemAttr_NC = '00';    // Non-cacheable
```

```
constant bits(2) MemAttr_WT = '10';    // Write-through
```

```
constant bits(2) MemAttr_WB = '11';    // Write-back
```

The allocation hints are defined as follows:

```
constant bits(2) MemHint_No = '00';    // No allocate
constant bits(2) MemHint_WA = '01';    // Write-allocate, Read-no-allocate
constant bits(2) MemHint_RA = '10';    // Read-allocate, Write-no-allocate
constant bits(2) MemHint_RWA = '11';   // Read-allocate and Write-allocate
```

The access permissions type is defined as follows:

```
type Permissions is (
    bits(3) ap,    // Access permission bits
    bit    xn,    // Execute-never bit
    bit    pxn    // Privileged execute-never bit
)
```

## G2.8.2 Basic memory access

The two `_Mem[]` accessors, Non-assignment (memory read) and Assignment (memory write), are the operations that perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

```
bits(8*size) _Mem[AddressDescriptor desc, integer size, AccType acctype];
_Mem[AddressDescriptor desc, integer size, AccType acctype] = bits(8*size) value;
```

The functions address the array using `desc.address` which supplies:

- A 48-bit physical address.
- A single NS bit to select between Secure and Non-secure parts of the array.

The `AccType` parameter describes the access type, such as normal, exclusive, ordered, and streaming. For a definition of `AccType`, see [Address space on page E2-2334](#).

The actual implemented array of memory might be smaller than the  $2^{48}$  bytes implied. In this case the scheme for aliasing is IMPLEMENTATION DEFINED, or some parts of the address space might give rise to external aborts or a System Error.

The attributes in `memaddrdesc.memattrs` are used by the memory system to determine caching and ordering behaviors as described in [Memory types and attributes on page E2-2357](#), [Memory ordering on page E2-2350](#), and [Atomicity in the ARM architecture on page E2-2346](#).

`PAMax()` returns the IMPLEMENTATION DEFINED size of the physical address.

```
integer PAMax();
```

### ———— Note —————

In AArch32 a translation regime can never generate more than 40 bits of an address.

---

## G2.8.3 Aligned memory access

The `MemA_with_type[]` function makes an atomic, little-endian accesses of size bytes.

```
// MemA_with_type[] - non-assignment (read) form
// =====
bits(size*8) MemA_with_type[bits(32) address, integer size, AccType acctype, boolean wasaligned]
    assert size IN {1, 2, 4, 8, 16};
    assert address == Align(address, size);

    AddressDescriptor memaddrdesc;
```

```

bits(size*8) value;
iswrite = FALSE;

// MMU or MPU
memaddrdesc = AArch32.TranslateAddress(address, acctype, iswrite, wasaligned, size);

// Check for aborts or debug exceptions
if IsFault(memaddrdesc) then
    AArch32.Abort(address, memaddrdesc.fault);

// Memory array access
value = _Mem[memaddrdesc, size, acctype];
return value;

// MemA_with_type[] - assignment (write) form
// =====

MemA_with_type[bits(32) address, integer size, AccType acctype, boolean wasaligned] = bits(size*8) value
assert size IN {1, 2, 4, 8, 16};
assert address == Align(address, size);

AddressDescriptor memaddrdesc;
iswrite = TRUE;

// MMU or MPU
memaddrdesc = AArch32.TranslateAddress(address, acctype, iswrite, wasaligned, size);

// Check for aborts or debug exceptions
if IsFault(memaddrdesc) then
    AArch32.Abort(address, memaddrdesc.fault);

// Effect on exclusives
if memaddrdesc.memattrs.shareable then
    ClearExclusiveByAddress(memaddrdesc.paddress, ProcessorID(), size);

// Memory array access
_Mem[memaddrdesc, size, acctype] = value;
return;

```

## G2.8.4 Unaligned memory access

The MemU\_with\_type[] function makes an access of the required type. If that access is architecturally defined to be atomic, it synthesizes accesses from multiple calls to MemA\_with\_type[] or multiple accesses, depending on whether the access is required to be atomic. It also reverses the byte order if the access is big-endian.

```

// MemU_with_type[] - non-assignment (read) form
// =====

bits(size*8) MemU_with_type[bits(32) address, integer size, AccType acctype]
assert size IN {1, 2, 4, 8, 16};
bits(size*8) value;
integer i;
boolean iswrite = FALSE;

aligned = AArch32.CheckAlignment(address, size, acctype, iswrite);

if !aligned then
    assert size > 1;
    value<7:0> = MemA_with_type[address, 1, acctype, aligned];

// For subsequent bytes it is CONSTRAINED UNPREDICTABLE whether an unaligned Device memory
// access will generate an Alignment Fault, as to get this far means the first byte did
// not, so we must be changing to a new translation page.
c = ConstrainUnpredictable();
assert c IN {Constraint_FAULT, Constraint_NONE};
if c == Constraint_NONE then aligned = TRUE;

```

```

        for i = 1 to size-1
            value<8*i+7:8*i> = MemA_with_type[address+i, 1, acctype, aligned];
    else
        value = MemA_with_type[address, size, acctype, aligned];

    if BigEndian() then
        value = BigEndianReverse(value);
    return value;

// MemU_with_type[] - assignment (write) form
// =====

MemU_with_type[bits(32) address, integer size, AccType acctype] = bits(size*8) value
integer i;
boolean iswrite = TRUE;

if BigEndian() then
    value = BigEndianReverse(value);

aligned = AArch32.CheckAlignment(address, size, acctype, iswrite);

if !aligned then
    assert size > 1;
    MemA_with_type[address, 1, acctype, aligned] = value<7:0>;

    // For subsequent bytes it is CONSTRAINED UNPREDICTABLE whether an unaligned Device memory
    // access will generate an Alignment Fault, as to get this far means the first byte did
    // not, so we must be changing to a new translation page.
    c = ConstrainUnpredictable();
    assert c IN {Constraint_FAULT, Constraint_NONE};
    if c == Constraint_NONE then aligned = TRUE;

    for i = 1 to size-1
        MemA_with_type[address+i, 1, acctype, aligned] = value<8*i+7:8*i>;
else
    MemA_with_type[address, size, acctype, aligned] = value;
return;

```

## G2.8.5 Exclusive monitors operations

The SetExclusiveMonitors() function sets the exclusive monitors for a Load-Exclusive instruction, for a block of bytes. The size of the blocks is determined by size, at the VA address. The ExclusiveMonitorsPass() function checks whether a Store-Exclusive instruction still has possession of the exclusive monitors and therefore completes successfully.

```

// AArch32.SetExclusiveMonitors()
// =====

// Sets the Exclusive Monitors for the current PE to record the addresses associated
// with the virtual address region of size bytes starting at address.

AArch32.SetExclusiveMonitors(bits(32) address, integer size)

    acctype = AccType_ATOMIC;
    iswrite = FALSE;
    aligned = (address != Align(address, size));

    memaddrdesc = AArch32.TranslateAddress(address, acctype, iswrite, aligned, size);

    // Check for aborts or debug exceptions
    if IsFault(memaddrdesc) then
        return;

    if memaddrdesc.memattrs.shareable then
        MarkExclusiveGlobal(memaddrdesc.paddress, ProcessorID(), size);

    MarkExclusiveLocal(memaddrdesc.paddress, ProcessorID(), size);

```

```
AArch32.MarkExclusiveVA(address, ProcessorID(), size);
```

The ExclusiveMonitorsPass() function checks whether a Store-Exclusive instruction still has possession of the exclusive monitors, by checking whether the exclusive monitors are set to include the location of the memory block specified by size, at the virtual address defined by address. The atomic write that follows after the exclusive monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to SetExclusiveMonitors().

```
// AArch32.ExclusiveMonitorsPass()
// =====

// Return TRUE if the Exclusive Monitors for the current PE include all of the addresses
// associated with the virtual address region of size bytes starting at address.
// The immediately following memory write must be to the same addresses.
```

```
boolean AArch32.ExclusiveMonitorsPass(bits(32) address, integer size)

    // It is IMPLEMENTATION DEFINED whether the detection of memory aborts happens
    // before or after the check on the local Exclusive Monitor. As a result a failure
    // of the local monitor can occur on some implementations even if the memory
    // access would give an memory abort.

    acctype = AccType_ATOMIC;
    iswrite = TRUE;
    aligned = (address == Align(address, size));

    if !aligned then
        secondstage = FALSE;
        AArch32.Abort(address, AArch32.AlignmentFault(acctype, iswrite, secondstage));

    passed = AArch32.IsExclusiveVA(address, ProcessorID(), size);
    if !passed then
        return FALSE;

    memaddrdesc = AArch32.TranslateAddress(address, acctype, iswrite, aligned, size);

    // Check for aborts or debug exceptions
    if IsFault(memaddrdesc) then
        AArch32.Abort(address, memaddrdesc.fault);

    passed = IsExclusiveLocal(memaddrdesc.paddress, ProcessorID(), size);
    if passed && memaddrdesc.memattrs.shareable then
        passed = IsExclusiveGlobal(memaddrdesc.paddress, ProcessorID(), size);

    if passed then
        ClearExclusiveLocal(ProcessorID());

    return passed;
```

The ExclusiveMonitorsStatus() function returns 0 if the previous atomic write was to the same physical memory locations selected by ExclusiveMonitorsPass() and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

```
bit ExclusiveMonitorsStatus();
```

The MarkExclusiveGlobal() procedure takes as arguments a FullAddress.paddress, the PE identifier processorid and the size of the transfer. The procedure records that the PE processorid has requested exclusive access covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

```
MarkExclusiveGlobal(FullAddress paddress, integer processorid, integer size);
```

The `MarkExclusiveLocal()` procedure takes as arguments a `FullAddr` address, the PE identifier `processorid` and the size of the transfer. The procedure records in a local record that PE `processorid` has requested exclusive access to an address covering at least `size` bytes from address `address`. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a `MarkExclusiveGlobal()` using the same parameters.

```
MarkExclusiveLocal(FullAddr address, integer processorid, integer size);
```

The `IsExclusiveGlobal()` function takes as arguments a `FullAddr` address, the PE identifier `processorid` and the size of the transfer. The function returns `TRUE` if the PE `processorid` has marked in a global record an address range as exclusive access requested that covers at least `size` bytes from address `address`. It is IMPLEMENTATION DEFINED whether it returns `TRUE` or `FALSE` if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, `IsExclusiveGlobal()` returns `FALSE`.

```
boolean IsExclusiveGlobal(FullAddr address, integer processorid, integer size);
```

The `IsExclusiveLocal()` function takes as arguments a `FullAddr` address, the PE identifier `processorid` and the size of the transfer. The function returns `TRUE` if the PE `processorid` has marked an address range as exclusive access requested that covers at least the `size` bytes from address `address`. It is IMPLEMENTATION DEFINED whether this function returns `TRUE` or `FALSE` if the address marked as exclusive access requested does not cover all of `size` bytes from address `address`. If no address is marked as exclusive access requested, then this function returns `FALSE`. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of `IsExclusiveGlobal()` with the same parameters.

```
boolean IsExclusiveLocal(FullAddr address, integer processorid, integer size);
```

The `ClearExclusiveByAddress()` procedure takes as arguments a `FullAddr` address, the PE identifier `processorid` and the size of the transfer. The procedure clears the global records of all PEs, other than `processorid`, for which an address region including any of `size` bytes starting from `address` has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE `processorid` is also cleared if any of `size` bytes starting from `address` has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

```
ClearExclusiveByAddress(FullAddr address, integer processorid, integer size);
```

The `ClearExclusiveLocal()` procedure takes as arguments the PE identifier `processorid`. The procedure clears the local record of PE `processorid` for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE `processorid` that an address has had a request for an exclusive access.

```
ClearExclusiveLocal(integer processorid);
```

## G2.8.6 Access permission checking

The function `CheckPermission()` is used by the architecture to perform access permission checking based on attributes derived from the translation tables or location descriptors.

The interpretation of access permission is shown in [Memory access control on page G3-3609](#).

The pseudocode function for checking access permissions is as follows:

```
// AArch32.CheckPermission()
// =====
// Function used for permission checking from AArch32 stage 1 translations

FaultRecord AArch32.CheckPermission(Permissions perms, bits(32) vaddress, integer level,
                                     bits(4) domain, bit NS, AccType acctype, boolean iswrite)
    assert ELUsingAArch32(TranslationRegime());

    if PSTATE.EL != EL2 then
        wxn = SCTLX.WXN == '1';
        if TTBCR.EAE == '1' || SCTLX.AFE == '1' || perms.ap<0> == '1' then
            priv_r = TRUE;
            priv_w = perms.ap<2> == '0';
```

```

        user_r = perms.ap<1> == '1';
        user_w = perms.ap<2:1> == '01';
    else
        priv_r = perms.ap<2:1> != '00';
        priv_w = perms.ap<2:1> == '01';
        user_r = perms.ap<1> == '1';
        user_w = FALSE;
    uwxn = SCTL.R.UWXN == '1';
    user_x = user_r && perms.xn == '0' && !(user_w && wxn);
    priv_x = (priv_r && perms.xn == '0' && perms.pxn == '0' &&
        !(priv_w && wxn) && !(user_w && uwxn));
    ispriv = PSTATE.EL == EL1 && acctype != AccType_UNPRIV;

    if ispriv then
        (r, w, x) = (priv_r, priv_w, priv_x);
    else
        (r, w, x) = (user_r, user_w, user_x);
else
    // Access from EL2
    wxn = HSCTLR.WXN == '1';
    r = TRUE;
    w = perms.ap<2> == '0';
    x = perms.xn == '0' && !(w && wxn);

    secure_instr_fetch = SCR_GEN[].SIF; // Restriction on Secure instruction fetch
    if HaveEL(EL3) && IsSecure() && NS == '1' && secure_instr_fetch == '1' then
        x = FALSE;

    if acctype == AccType_IFETCH then
        fail = !x;
    elseif iswrite then
        fail = !w;
    else
        fail = !r;

    if fail then
        secondstage = FALSE;
        s2fs1walk = FALSE;
        ipaddress = bits(40) UNKNOWN;
        return AArch32.PermissionFault(ipaddress, domain, level, acctype, iswrite, secondstage,
            s2fs1walk);
    else
        return AArch32.NoFault();

```

## G2.8.7 Abort exceptions

The Abort() function generates a Data Abort exception or a Prefetch Abort exception by calling the TakeDataAbortException() or TakePrefetchAbortException() function.

```

// AArch32.Abort()
// =====
// Abort and Debug exception handling in an AArch32 translation regime.

AArch32.Abort(bits(32) vaddress, FaultRecord fault)

    route_to_monitor = HaveEL(EL3) && SCR_GEN[].EA == '1' && IsExternalAbort(fault);
    route_to_hyp = (AArch32.GeneralExceptionsToHyp() || IsSecondStage(fault) ||
        (HaveEL(EL2) && !IsSecure() && IsDebugException(fault) && HDCR.TDE == '1'));

    if (route_to_monitor && !ELUsingAArch32(EL3)) || (route_to_hyp && !ELUsingAArch32(EL2)) then
        AArch64.Abort(ZeroExtend(vaddress), fault);

    if fault.acctype == AccType_IFETCH then
        AArch32.TakePrefetchAbortException(vaddress, fault);
    else
        AArch32.TakeDataAbortException(vaddress, fault);

```

The FaultRecord type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. [Pseudocode details of VMSAv8-32 memory system operations on page G3-3755](#) provides a number of wrappers to generate a FaultRecord.

The NoFault() function returns a null record that indicates no fault. The IsFault() function tests whether a FaultRecord contains a fault.

```

enumeration Fault {Fault_None,
                    Fault_AccessFlag,
                    Fault_Alignment,
                    Fault_Background,
                    Fault_Domain,
                    Fault_Permission,
                    Fault_Translation,
                    Fault_AddressSize,
                    Fault_SyncExternal,
                    Fault_SyncExternalOnWalk,
                    Fault_SyncParity,
                    Fault_SyncParityOnWalk,
                    Fault_AsyncParity,
                    Fault_AsyncExternal,
                    Fault_Debug,
                    Fault_TLBConflict,
                    Fault_Lockdown,
                    Fault_Coproc,
                    Fault_ICacheMaint};

type FaultRecord is (Fault   type,           // Fault Status
                    AccType acctype,        // Type of access that faulted
                    bits(48) ipaddress,     // Intermediate physical address
                    boolean  s2fs1walk,    // Is on a Stage 1 page table walk
                    boolean  write,         // TRUE for a read, FALSE for a write
                    integer  level,        // For translation, access flag and permission faults
                    bit      extflag,      // IMPLEMENTATION DEFINED syndrome for external aborts
                    boolean  secondstage,  // Is a Stage 2 abort
                    bits(4)  domain,      // Domain number, AArch32 only
                    bits(4)  debugmoe)    // Debug method of entry, from AArch32 only

// AArch32.NoFault()
// =====

FaultRecord AArch32.NoFault()

    ipaddress = bits(40) UNKNOWN;
    domain = bits(4) UNKNOWN;
    level = integer UNKNOWN;
    acctype = AccType_NORMAL;
    iswrite = boolean UNKNOWN;
    extflag = bit UNKNOWN;
    debugmoe = bits(4) UNKNOWN;
    secondstage = FALSE;
    s2fs1walk = FALSE;

    return AArch32.CreateFaultRecord(Fault_None, ipaddress, domain, level, acctype, iswrite,
                                     extflag, debugmoe, secondstage, s2fs1walk);

// IsFault()
// =====
// Return true if a fault is associated with an address descriptor

boolean IsFault(AddressDescriptor addrdesc)
    return addrdesc.fault.type != Fault_None;

```

## G2.8.8 Memory barriers

The definition for the memory barrier functions is:

```

enumeration MReqDomain {MReqDomain_Nonshareable, MReqDomain_InnerShareable,
                       MReqDomain_OuterShareable, MReqDomain_FullSystem};

```

```
enumeration MBReqTypes    {MBReqTypes_Reads, MBReqTypes_Writes, MBReqTypes_A11};
```

These functions define the required shareability domains and required access types used as arguments for DMB and DSB instructions.

The following procedures perform the memory barriers:

```
DataMemoryBarrier(MBReqDomain domain, MBReqTypes types);
```

```
DataSynchronizationBarrier(MBReqDomain domain, MBReqTypes types);
```

```
InstructionSynchronizationBarrier();
```

# Chapter G3

## The AArch32 Virtual Memory System Architecture

This chapter describes the ARMv8-A AArch32 Virtual Memory System Architecture (VMSA), that is backwards-compatible with VMSAv7. It includes the following section.

- *Execution privilege, Exception levels, and AArch32 Privilege levels* on page G3-3560.
- *About VMSAv8-32* on page G3-3562.
- *The effects of disabling address translation stages on VMSAv8-32 behavior* on page G3-3569.
- *Translation tables* on page G3-3573.
- *The VMSAv8-32 Short-descriptor translation table format* on page G3-3578.
- *The VMSAv8-32 Long-descriptor translation table format* on page G3-3591.
- *Memory access control* on page G3-3609.
- *Memory region attributes* on page G3-3618.
- *Translation Lookaside Buffers (TLBs)* on page G3-3630.
- *TLB maintenance requirements* on page G3-3633.
- *Caches in VMSAv8-32* on page G3-3644.
- *VMSAv8-32 memory aborts* on page G3-3647.
- *Exception reporting in a VMSAv8-32 implementation* on page G3-3659.
- *Virtual Address to Physical Address translation operations* on page G3-3685.
- *About the System registers for VMSAv8-32* on page G3-3691.
- *Organization of the CP14 registers in VMSAv8-32* on page G3-3713.
- *Organization of the CP15 registers in VMSAv8-32* on page G3-3716.
- *Functional grouping of VMSAv8-32 System registers* on page G3-3735.
- *Pseudocode details of VMSAv8-32 memory system operations* on page G3-3755.

———— **Note** —————

This chapter must be read with [Chapter G2 The AArch32 System Level Memory Model](#).

### G3.1 Execution privilege, Exception levels, and AArch32 Privilege levels

In ARMv8, the hierarchy of software execution privilege, within a particular Security state, is defined by the Exception levels, with higher Exception level numbers indicating higher privilege. Table G3-1 shows this hierarchy for each Security state.

**Table G3-1 Execution privilege and Exception levels, by Security state**

Execution privilege	Secure state	Non-secure state	Typical use
Highest	EL3	- <sup>a</sup>	Secure monitor
-	- <sup>a</sup>	EL2	Hypervisor
-	EL1	EL1	Secure or Non-secure OS
Lowest, Unprivileged	EL0	EL0	Secure or Non-secure application

a. EL2 is never implemented in Secure state, and EL3 is never implemented in Non-secure state.

When executing in AArch32 state, within a given Security state, the current PE state, including the execution privilege, is primarily indicated by the current *PE mode*. In Secure state, how the PE modes map onto the Exception levels depends on whether EL3 is using AArch32 or is using AArch64, and:

- Figure G1-1 on page G1-3408 shows this mapping when EL3 is using AArch32.
- Figure G1-2 on page G1-3415 shows this mapping when EL3 is using AArch64.

Table G3-2 shows this mapping. In interpreting this table:

- Monitor mode is implemented only in Secure state, and only if EL3 is using AArch32.
- Hyp mode is implemented only in Non-secure state, and only if EL2 is using AArch32.
- System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented:
  - In Secure state** If either:
    - EL3 is using AArch32.
    - EL3 is using AArch64 and EL1 is using AArch32.
  - In Non-secure state** If EL1 is using AArch32.
- User mode is implemented if EL0 is using AArch32.

**Table G3-2 Mapping of AArch32 PE modes to Exception levels**

Exception level	PE modes in the given Security state, and EL3 Execution state		
	Secure state, EL3 using AArch32	Secure state, EL3 using AArch64	Non-secure state
EL3	Monitor, System, FIQ, IRQ, Supervisor, Abort, Undefined	-	-
EL2	-	-	Hyp
EL1	-	System, FIQ, IRQ, Supervisor, Abort, Undefined	System, FIQ, IRQ, Supervisor, Abort, Undefined
EL0	User	User	User

Because AArch32 behavior is described in terms of the PE modes, and transitions between PE modes, the Exception levels are implicit in most of the description of operation in AArch32 state.

However, the *translation regimes* provided by the VMSA cannot be described only in terms of the PE modes. In AArch64 state these regimes are defined by the Exception levels that use them. However, in AArch32 state this would result in descriptions that, for Secure state operation in modes other than User mode, would depend on the Exception level being used by AArch32.

To provide a consistent description of address translation as seen from AArch32 state, the translation regimes are described in terms of the Privilege levels originally defined in the ARMv7 descriptions of AArch32 state. [Table G3-3](#) shows this.

**Table G3-3 Mapping of PE modes to AArch32 Privilege levels**

Privilege level	Secure state	Non-secure state
PL2	-	Hyp <sup>a</sup>
PL1	Monitor <sup>b</sup> , System, FIQ, IRQ, Supervisor, Abort, Undefined	System, FIQ, IRQ, Supervisor, Abort, Undefined
PL0	User	User

a. Implemented only in Non-secure state, and only if EL2 is using AArch32

b. Implemented only in Secure state, and only if EL3 is using AArch32.

Comparing [Table G3-3](#) with [Table G3-2 on page G3-3560](#) shows that:

**In Non-secure state**

Each privilege level maps to the corresponding Exception level. For example PL1 maps to EL1.

**In Secure state**

PL0 maps to EL0.

The mapping of PL1 depends on the Execution state being used by EL3, as follows:

**EL3 using AArch64** Secure PL1 maps to Secure EL1. Monitor mode is not implemented.

**EL3 using AArch32** Secure PL1 maps to Secure EL3. Monitor mode is implemented as one of the Secure PL1 modes.

## G3.2 About VMSAv8-32

### Note

- This chapter describes the ARMv8 VMSA for AArch32 state, VMSAv8-32. This is generally equivalent to VMSAv7 for an implementation that includes all of the Security Extensions, the Multiprocessing Extension, the Large Physical Address Extension, and the Virtualization Extensions.
- This chapter describes the control of the VMSA by Exception levels that are using AArch32. [Execution privilege, Exception levels, and AArch32 Privilege levels on page G3-3560](#) summarizes how the AArch32 PE modes map onto the Exception levels.  
[Chapter D5 The AArch64 Virtual Memory System Architecture](#) describes the control of the VMSA by exception levels that are using AArch64.
- For details of the VMSA differences in previous versions of the ARM architecture see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

The main function of the VMSA is to perform address translation, and access permissions and memory attribute determination and checking, for memory accesses made by the PE. Address translation, and permissions and attribute determination and checking, is performed by a *stage* of address translation.

In VMSAv8-32, the *Memory Management Unit* (MMU) provides a number of stages of address translation. This chapter describes only the stages that are visible from Exception levels that are using AArch32, which are as follows:

#### For operation in Secure state

A single stage of address translation, for use when executing at PL1 or PL0. This is the *Secure PL1&0 stage 1* address translation stage.

#### For operation in Non-secure state

- A single stage of address translation for use when executing at PL2. This is the *Non-secure PL2 stage 1* address translation stage.
- Two stages of address translation for use when executing at PL1 or PL0. These are:
  - The *Non-secure PL1&0 stage 1* address translation stage.
  - The *Non-secure PL1&0 stage 2* address translation stage.

The System registers provide independent control of each supported stage of address translation, including a control to disable that stage of translation.

These features mean the VMSAv8-32 can support a hierarchy of software supervision, for example an Operating System and a hypervisor.

Each stage of address translation uses address translations and associated memory properties held in memory mapped tables called *translation tables*.

For information about how the MMU features differ if an implementation does not include all of the Exception levels, see [About address translation for VMSAv8-32 on page G3-3565](#).

The translation tables define the following properties:

#### Access to the Secure or Non-secure address map

The translation table entries determine whether an access from Secure state accesses the Secure or the Non-secure address map. Any access from Non-secure state accesses the Non-secure address map.

#### Memory access permission control

This controls whether a program is permitted to access a memory region. For instruction and data access, the possible settings are:

- No access.
- Read-only.

- Write-only. This is possible only in a translation regime with two stages of translation.
- Read/write.

For instruction accesses, additional controls determine whether instructions can be fetched and executed from the memory region.

If a PE attempts an access that is not permitted, a memory fault is signaled to the PE.

### Memory region attributes

These describe the properties of a memory region. The top-level attribute, the Memory type, is one of Normal, or a type of Device memory, as follows:

- Both translation table formats support the following Device memory types:
  - Device-nGnRnE
  - Device-nGnRE
- The Long-descriptor translation table format supports, in addition, the following Device memory types:
  - Device-nGRE
  - Device-GRE

#### ———— Note ————

ARMv8 added the Device-nGRE and Device-GRE memory types. Also, in versions of the ARM architecture before ARMv8:

- Device-nGnRnE memory is described as Strongly-ordered memory.
- Device-nGnRE memory is described as Device memory.

Normal memory regions can have additional attributes.

For more information, see [Memory types and attributes on page E2-2357](#).

### Address translation mappings

An address translation maps an *input address* to an *output address*.

A stage 1 translation takes the address of an explicit data access or instruction fetch, a *virtual address* (VA), as the input address, and translates it to a different output address:

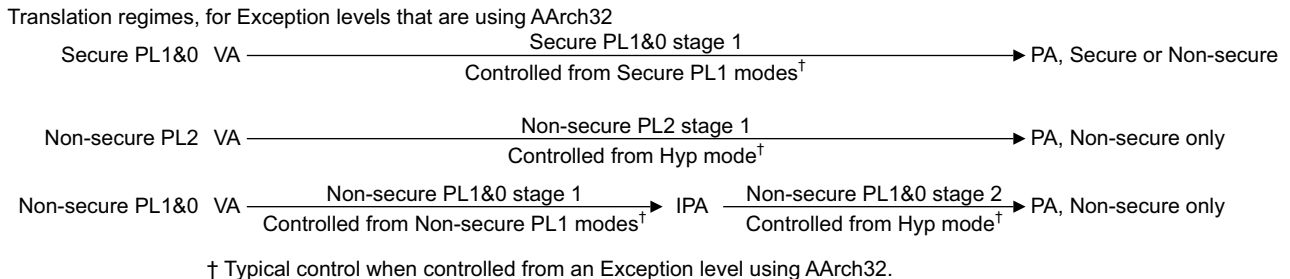

- If only one stage of translation is provided, this output address is the *physical address* (PA).
- If two stages of address translation are provided, the output address of the stage 1 translation is an *intermediate physical address* (IPA).

#### ———— Note ————

In the ARMv8-32 architecture, a software agent, such as an Operating System, that uses or defines stage 1 memory translations, might be unaware of the distinction between IPA and PA.

A stage 2 translation translates the IPA to a PA.

The possible security states and privilege levels of memory accesses define a set of *translation regimes*. [Figure G3-1](#) shows the VMSAv8-32 translation regimes, and their associated translation stages and the Exception levels from which they are controlled.

**Figure G3-1 VMSAv8-32 translation regimes, and associated control**

---

**Note**

---

Conceptually, a translation regime that has only a stage 1 address translation is equivalent to a regime with a fixed, flat stage 2 mapping from IPA to PA.

---

System registers control VMSAv8-32, including defining the location of the translation tables, and enabling and configuring the MMU, including enabling and disabling the different address translation stages. Also, they report any faults that occur on a memory access. For more information, see [Functional grouping of VMSAv8-32 System registers](#) on page G3-3735.

The following sections give an overview of VMSAv8-32, and of the implementation options for VMSAv8-32:

- [Address types used in a VMSAv8-32 description.](#)
- [Address spaces in VMSAv8-32.](#)
- [About address translation for VMSAv8-32](#) on page G3-3565.

The remainder of the chapter fully describes the VMSA, including the different implementation options, as summarized in [Organization of this chapter](#) on page G3-3567.

### G3.2.1 Address types used in a VMSAv8-32 description

A description of VMSAv8-32 refers to the following address types.

---

**Note**

---

These descriptions relate to a VMSAv8-32 description and therefore sometimes differ from the generic definitions given in the Glossary.

---

#### Virtual Address (VA)

An address used in an instruction, as a data or instruction address, is a Virtual Address (VA).

An address held in the PC, LR, or SP, is a VA.

The VA map runs from zero to the size of the VA space. For AArch32 state, the maximum VA space is 4GB, giving a maximum VA range of 0x00000000-0xFFFFFFFF.

#### Intermediate Physical Address (IPA)

In a translation regime that provides two stages of address translation, the IPA is the address after the stage 1 translation, and is the input address for the stage 2 translation.

In a translation regime that provides only one stage of address translation, the IPA is identical to the PA.

A VMSAv8-32 implementation provides only one stage of address translation:

- If the implementation does not include EL2.
- When executing in Secure state.
- When executing in Hyp mode.

#### Physical Address (PA)

The address of a location in the Secure or Non-secure memory map. That is, an output address from the PE to the memory system.

### G3.2.2 Address spaces in VMSAv8-32

For execution in AArch32 state, the ARMv8 architecture supports:

- A VA space of up to 32 bits. The actual width is IMPLEMENTATION DEFINED.
- An IPA space of up to 40 bits. The translation tables and associated System registers define the width of the implemented address space.

**Note**

AArch32 defines two translation table formats. The *Long-descriptor* format gives access to the full 40-bit IPA or PA space at a granularity of 4KB. The *Short-descriptor* format:

- Gives access to a 32-bit PA space at 4KB granularity.
- Gives access to a 40-bit PA space, but only at 16MB granularity, by the use of Supersections.

If an implementation includes EL3, the address maps are defined independently for Secure and Non-secure operation, providing two independent 40-bit address spaces, where:

- A VA accessed from Non-secure state can only be translated to the Non-secure address map.
- A VA accessed from Secure state can be translated to either the Secure or the Non-secure address map.

**G3.2.3 About address translation for VMSAv8-32**

Address translation is the process of mapping one address type to another, for example, mapping VAs to IPAs, or mapping VAs to PAs. A *translation table* defines the mapping from one address type to another, and a *Translation table base register* indicates the start of a translation table. Each implemented stage of address translation shown in [Figure G3-1 on page G3-3563](#) requires its own translation tables.

For PL1&0 stage 1 translations, the mapping can be split between two tables, one controlling the lower part of the VA space, and the other controlling the upper part of the VA space. This can be used, for example, so that:

- One table defines the mapping for operating system and I/O addresses, that do not change on a context switch.
- A second table defines the mapping for application-specific addresses, and therefore might require updating on a context switch.

The VMSAv8-32 implementation options determine the supported address translation stages. The following descriptions apply when all implemented Exception levels are using AArch32:

**VMSAv8-32 without EL2 or EL3**

Supports only a single PL1&0 stage 1 address translation. Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by [TTBR0](#) and [TTBR1](#), and controlled by [TTBCR](#).

**VMSAv8-32 with EL3 but without EL2**

Supports only the Secure PL1&0 stage 1 address translation and the Non-secure PL1&0 stage 1 address translation. In each security state, this stage of translation can be split between two sets of translation tables, with base addresses defined by the Secure and Non-secure copies of [TTBR0](#) and [TTBR1](#), and controlled by the Secure and Non-secure copies of [TTBCR](#).

**VMSAv8-32 with EL2 but without EL3**

The implementation supports the following stages of address translation:

**Non-secure PL2 stage 1 address translation**

The [HTTBR](#) defines the base address of the translation table for this stage of address translation, controlled by [HTCR](#).

**Non-secure PL1&0 stage 1 address translation**

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of [TTBR0](#) and [TTBR1](#) and controlled by the Non-secure instance of [TTBCR](#).

**Non-secure PL1&0 stage 2 address translation**

The [VTTBR](#) defines the base address of the translation table for this stage of address translation, controlled by [VTCR](#).

**VMSAv8-32 with EL2 and EL3**

The implementation supports all of the stages of address translation, as follows:

**Secure PL1&0 stage 1 address translation**

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Secure copies of **TTBR0** and **TTBR1**, and controlled by the Secure instance of **TTBCR**.

**Non-secure PL2 stage 1 address translation**

The **HTTBR** defines the base address of the translation table for this stage of address translation, controlled by **HTCR**.

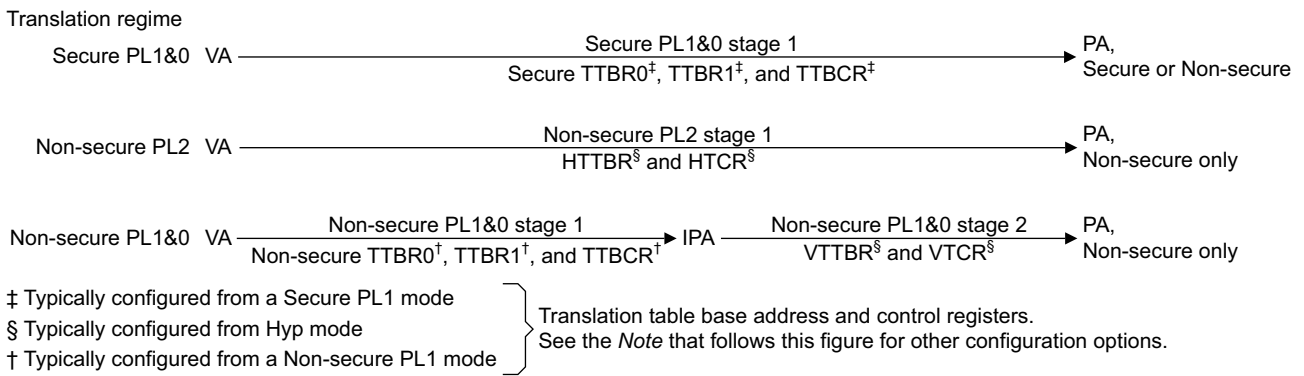

**Non-secure PL1&0 stage 1 address translation**

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of **TTBR0** and **TTBR1** and controlled by the Non-secure instance of **TTBCR**.

**Non-secure PL1&0 stage 2 address translation**

The **VTTBR** defines the base address of the translation table for this stage of address translation, controlled by **VTCT**.

Figure G3-2 shows the translation regimes and stages in a VMSAv8-32 implementation that includes all of the Exception levels, and indicates the PE mode that, typically, defines each set of translation tables, if that stage of address translation is controlled by a Privilege level that is using AArch32:

**Figure G3-2 VMSAv8-32 address translation summary**

**Note**

The term *Typically configured* is used in Figure G3-2 to indicate the expected software usage. However, stages of address translation used in AArch32 state can also be configured:

- From an Exception level higher than the Exception level of the configuring PE mode shown in Figure G3-2, regardless of whether that Exception level is using AArch32 or is using AArch64, except that a Non-secure Exception level can never configure a stage of address translation that is used in Secure state.
- From an Exception level that is using AArch64 and is higher than the level at which the translation stage is being used. For example, if Non-secure EL0 is the only Non-secure Exception level that is using AArch32, then the Non-secure PL1&0 stage of address translation is configured from Non-secure EL1, that is using AArch64.

In general:

- The translation from VA to PA can require multiple *stages* of address translation, as Figure G3-2 shows.
- A single stage of address translation takes an *input address* and translates it to an *output address*.

A full translation table lookup is called a *translation table walk*. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single input address to output address translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a *level* of address lookup. The final level of the lookup defines:

- The required output address.
- The *attributes* and *access permissions* of the addressed memory.

*Translation Lookaside Buffers* (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and VMSAv8-32 provides TLB maintenance operations for the management of TLB contents.

———— **Note** ————

The ARM architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.

To reduce the software overhead of TLB maintenance, for the PL1&0 translation regimes VMSAv8-32 distinguishes between *Global pages* and *Process-specific pages*. The *Address Space Identifier* (ASID) identifies pages associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures.

If an implementation includes EL2, the *virtual machine identifier* (VMID) identifies the current virtual machine, with its own independent ASID space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another, if the virtual machines have different VMIDs. For stage 2 translations, all translations are associated with the current VMID. There is no mechanism to associate a particular stage 2 translation with multiple virtual machines.

## G3.2.4 Organization of this chapter

The remainder of this chapter is organized as follows.

The first part of the chapter describes address translation and the associated memory properties held in the translation table entries, in the following sections:

- [The effects of disabling address translation stages on VMSAv8-32 behavior on page G3-3569.](#)
- [Translation tables on page G3-3573.](#)
- [Secure and Non-secure address spaces on page G3-3576.](#)
- [The VMSAv8-32 Short-descriptor translation table format on page G3-3578.](#)
- [The VMSAv8-32 Long-descriptor translation table format on page G3-3591.](#)
- [Memory access control on page G3-3609.](#)
- [Memory region attributes on page G3-3618.](#)
- [Translation Lookaside Buffers \(TLBs\) on page G3-3630.](#)
- [TLB maintenance requirements on page G3-3633.](#)

[Caches in VMSAv8-32 on page G3-3644](#) describes VMSAv8-32-specific cache requirements.

The following sections describe aborts on VMSAv8-32 memory accesses, and how these and other faults are reported:

- [VMSAv8-32 memory aborts on page G3-3647.](#)
- [Exception reporting in a VMSAv8-32 implementation on page G3-3659.](#)

[Virtual Address to Physical Address translation operations on page G3-3685](#) describes these operations, and how they relate to address translation.

A number of sections then describe the System registers for VMSAv8-32. The following sections give general information about the System registers, and the organization of the registers in the two coprocessor encoding spaces, CP14 and CP15, that provide the interface to these registers:

- [About the System registers for VMSAv8-32 on page G3-3691.](#)
- [Organization of the CP14 registers in VMSAv8-32 on page G3-3713.](#)
- [Organization of the CP15 registers in VMSAv8-32 on page G3-3716.](#)

- *Functional grouping of VMSAv8-32 System registers on page G3-3735.*

The following sections then describe each of the functional groups of CP15 registers, including a full description of each register in the group:

- *Identification registers, functional group on page G3-3736.*
- *Virtual memory control registers, functional group on page G3-3737.*
- *Exception and fault handling registers, functional group on page G3-3741.*
- *Other system control registers, functional group on page G3-3737.*
- *Lockdown, DMA, and TCM features, functional group on page G3-3747.*
- *Cache maintenance operations, functional group on page G3-3743.*
- *TLB maintenance operations, functional group on page G3-3744.*
- *Address translation operations, functional group on page G3-3745.*
- *Legacy feature registers, functional group on page G3-3750.*
- *Performance Monitors Extension registers, functional group on page G3-3747.*
- *Security registers, functional group on page G3-3741.*
- *Virtualization registers, functional group on page G3-3738.*
- *IMPLEMENTATION DEFINED registers, functional group on page G3-3751.*

*Pseudocode details of VMSAv8-32 memory system operations on page G3-3755* then describes many feature of VMSAv8-32 operation.

## G3.3 The effects of disabling address translation stages on VMSAv8-32 behavior

*About VMSAv8-32 on page G3-3562* defines the translation regimes and the associated stages of address translation, each of which has its own System registers for control and configuration. VMSAv8-32 includes an enable bit for each stage of address translation, as follows:

- **SCTLR.M**, in the Secure instance of the register, controls Secure PL1&0 stage 1 address translation.
- **SCTLR.M**, in the Non-secure instance of the register, controls Non-secure PL1&0 stage 1 address translation.
- **HCR.VM** controls Non-secure PL1&0 stage 2 address translation.
- **HSCTLR.M** controls Non-secure PL2 stage 1 address translation.

---

### Note

- The descriptions throughout this chapter describe address translation as seen by Exception levels that are using AArch32. However, for the Non-secure PL1&0 translation regime, the stage 2 translation:
  - Is controlled by the **HCR** if EL2 is using AArch32.
  - Is controlled by the **HCR\_EL2** if EL2 is using AArch64.For this reason, links to the **HCR** link to a table that disambiguates between the AArch32 **HCR** and the AArch64 **HCR\_EL2**.
- If EL2 is using AArch64, then the equivalent of the Non-secure PL2 translation regime is described in *Chapter D5 The AArch64 Virtual Memory System Architecture*, not in this chapter.

---

The following sections describe the effect on VMSAv8-32 behavior of disabling each stage of translation:

- *VMSAv8-32 behavior when stage 1 address translation is disabled.*
- *VMSAv8-32 behavior when stage 2 address translation is disabled on page G3-3571.*
- *Behavior of instruction fetches when all associated address translations are disabled on page G3-3571.*

*Enabling stages of address translation on page G3-3572* gives more information about each stage of address translation, in particular after a reset on an implementation that includes EL3.

### G3.3.1 VMSAv8-32 behavior when stage 1 address translation is disabled

When stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of address translation are treated as follows:

#### Non-secure PL1 and PL0 accesses when EL2 is implemented and HCR.DC is set to 1

In an implementation that includes EL2, for an access from a Non-secure PL1 or PL0 mode when **HCR.DC** is set to 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Write-Allocate, Outer Write-Back Write-Allocate memory attributes.

See also *Effect of the HCR.DC bit on page G3-3570*.

#### All other accesses

For all other accesses, when a stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

##### Data access

The stage 1 translation assigns the Device-nGnRnE memory type.

---

### Note

This means the access is Non-cacheable. Unexpected data cache hit behavior is IMPLEMENTATION DEFINED.

---

### Instruction access

The stage 1 translation assigns Normal memory attribute, with the cacheability and shareability attributes determined by the value of:

- The Secure instance of **SCTLR.I** for the Secure PL1&0 translation regime.
- The Non-secure instance of **SCTLR.I** for the Non-secure PL1&0 translation regime.
- **HSCTLR.I** for the Non-secure PL2 translation regime.

In these cases, the meaning of the I bit is as follows:

#### When I is set to 0

The stage 1 translation assigns the attributes Outer Shareable, Non-cacheable.

#### When I is set to 1

The stage 1 translation assigns the attributes Inner Write-Through no Write-Allocate, Outer Write-Through no Write-Allocate Cacheable.

#### Note

On some implementations, if the **SCTLR.TRE** bit is set to 0 then this behavior can be changed by the remap settings in the memory remap registers. The details of **TEX** remap when **SCTLR.TRE** is set to 0 are IMPLEMENTATION DEFINED, see [SCTLR.TRE](#), [SCTLR.M](#), and [the effect of the TEX remap registers on page G3-3623](#).

For this stage of translation, no memory access permission checks are performed, and therefore no MMU faults relating to this stage of translation can be generated.

#### Note

Alignment checking is performed, and therefore Alignment faults can occur.

For every access, when stage 1 translation is disabled, the output address of the stage 1 translation is equal to the input address. This is called a flat address mapping. If the implementation supports output addresses of more than 32 bits then the output address bits above bit[31] are zero. For example, for a VA to PA translation on an implementation that supports 40-bit PAs, PA[39:32] is 0x00.

For a Non-secure PL1 or PL0 access, if the PL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

See also [Behavior of instruction fetches when all associated address translations are disabled on page G3-3571](#).

### Effect of the HCR.DC bit

The **HCR.DC** bit determines the default memory attributes assigned for the first stage of the Non-secure PL1&0 translation regime when that stage of translation is disabled.

When executing in a Non-secure PL1 or PL0 mode with **HCR.DC** set to 1:

- For all purposes other than reading the value of the **SCTLR**, the PE behaves as if the value of the **SCTLR.M** bit is 0. This means Non-secure PL1&0 stage 1 address translation is disabled.
- For all purposes other than reading the value of the **HCR**, the PE behaves as if the value of the **HCR.VM** bit is 1. This means Non-secure PL1&0 stage 2 address translation is enabled.

The effect of **HCR.DC** might be held in TLB entries associated with a particular VMID. Therefore, if software executing at EL2 changes the **HCR.DC** value without also changing the current VMID, it must also invalidate all TLB entries associated with the current VMID. Otherwise, the behavior of Non-secure software executing at EL1 or ELO is UNPREDICTABLE.

## Effect of disabling translation on maintenance and address translation operations

Cache maintenance operations act on the target cache whether address translation is enabled or not, and regardless of the values of the memory attributes. However, if a stage of translation is disabled, they use the flat address mapping for that stage, and all mappings are considered global.

TLB invalidate operations act on the target TLB whether address translation is enabled or not.

When the Non-secure PL1&0 stage 1 address translation is disabled, any ATS1C\*\* or ATS12NSO\*\* address translation operation that accesses the Non-secure state translation reflects the effect of the HCR.DC bit. For more information about these operations see [Virtual Address to Physical Address translation operations on page G3-3685](#).

### G3.3.2 VMSAv8-32 behavior when stage 2 address translation is disabled

When stage 2 address translation is disabled:

- The IPA output from the stage 1 translation maps flat to the PA
- The memory attributes and permissions from the stage 1 translation apply to the PA.

If the stage 1 address translation and the stage 2 address translation are both disabled, see [Behavior of instruction fetches when all associated address translations are disabled](#).

### G3.3.3 Behavior of instruction fetches when all associated address translations are disabled

The information in this section applies to memory accesses:

- From Secure PL1 and PL0 modes, when the Secure PL1&0 stage 1 address translation is disabled
- From Hyp mode, when the Non-secure PL2 stage 1 address translation is disabled
- From Non-secure PL1 and PL0 modes, when all of the following apply:
  - The Non-secure PL1&0 stage 1 address translation is disabled.
  - The Non-secure PL1&0 stage 2 address translation is disabled.
  - HCR.DC is set to 0.

In these cases, a memory location might be accessed as a result of an instruction fetch if one of the following conditions is met:

- The memory location is in the same 4KB block of memory (aligned to 4KB) as an instruction that a simple sequential execution of the program requires to be fetched, or is in the 4KB block of memory immediately following such a block.
- The memory location is in the same 4KB block of memory (aligned to 4KB) from which a simple sequential execution of the program with all associated stages of address translation disabled has previously required an instruction to be fetched, or is in the 4KB block immediately following such a block.

These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.

#### ————— **Note** —————

To ensure architectural compliance, software must ensure that both of the following apply:

- Instructions that will be executed when address translation is disabled are located in 4KB blocks of the address space that contain only memory that is tolerant to speculative accesses.
- Each 4KB block of the address space that immediately follows a 4KB block that holds instructions that will be executed when address translation is disabled also contains only memory that is tolerant to speculative accesses.

### G3.3.4 Enabling stages of address translation

On powerup or reset, only the **SCTLR.M** bit for the Exception level and Security state entered on reset is reset to 0, disabling address translation for the initial state of the PE. All other **SCTLR.M** and **HSCTLR.M** bits that are implemented are UNKNOWN after the reset.

This means, on powerup or reset:

- On an implementation that includes EL3, where EL3 is using AArch32:
  - The PL1&0 stage 1 address translation enable bit, **SCTLR.M**, is Banked, meaning there are separate enables for operation in Secure and Non-secure state.
  - If EL3 is using AArch32, only the Secure instance of the **SCTLR.M** bit resets to 0, disabling the Secure state PL1&0 stage 1 address translation. The reset value of the Non-secure instance of **SCTLR.M** is UNKNOWN.
- On an implementation that includes EL2, where EL2 is using AArch32, the **HSCTLR.M** bit, that controls the Non-secure PL2 stage 1 address translation:
  - If the implementation does not include EL3, resets to 0.
  - Otherwise, is UNKNOWN.
- On an implementation that does not include either EL2 or EL3, there is a single stage of translation. This is controlled by **SCTLR.M**, that resets to 0.

———— **Note** —————

If, for the software that enables or disables a stage of address translation, the input address of a stage 1 translation differs from the output address of that stage 1 translation, and the software is running in translation regime that is affected by that stage of translation, then the requirement to synchronize changes to the system registers means it is uncertain where in the instruction stream the change of the translation takes place. For this reason, ARM strongly recommends that the input address and the output address are identical in this situation.

---

## G3.4 Translation tables

VMSAv8-32 defines two alternative translation table formats:

### Short-descriptor format

It uses 32-bit descriptor entries in the translation tables, and provides:

- Up to two levels of address lookup.
- 32-bit input addresses.
- Output addresses of up to 40 bits.
- Support for PAs of more than 32 bits by use of supersections, with 16MB granularity.
- Support for No access, Client, and Manager domains.

### Long-descriptor format

It uses 64-bit descriptor entries in the translation tables, and provides:

- Up to three levels of address lookup.
- Input addresses of up to 40 bits, when used for stage 2 translations.
- Output addresses of up to 40 bits.
- 4KB assignment granularity across the entire PA range.
- No support for domains, all memory regions are treated as in a Client domain.
- Fixed 4KB table size, unless truncated by the size of the input address space.

#### Note

- Translation with a 40-bit input address range requires two concatenated 4KB top-level tables, aligned to 8KB.
- The VMASv8-64 Long-descriptor translation table format is generally similar to this format, but supports input and output addresses of up to 48 bits, and has an assignment granularity and table size defined by its *translation granule*. This can be 4KB, 16KB, or 64KB. See [The VMSAv8-64 translation table format on page D5-1733](#).

In all implementations, of the possible address translations shown in [Figure G3-2 on page G3-3566](#), for stages of address translation that are using AArch32:

- In a particular Security state, the translation tables for the PL1&0 stage 1 translations can use either translation table format, and the `TTBCR.EAE` bit indicates the current translation table format.
- The translation tables for the Non-secure PL2 stage 1 translations, and for the Non-secure PL1&0 stage 2 translations, must use the Long-descriptor translation table format.

Many aspects of performing a translation table walk depend on the current translation table format. Therefore, the following sections describe the two formats, including how the MMU performs a translation table walk for each format:

- [The VMSAv8-32 Short-descriptor translation table format on page G3-3578](#).
- [The VMSAv8-32 Long-descriptor translation table format on page G3-3591](#).

The following subsections describe aspects of the translation tables and translation table walks, for memory accesses from AArch32 state, that are independent of the translation table format:

- [Translation table walks for memory accesses using VMSAv8-32 translation regimes on page G3-3574](#).
- [Information returned by a translation table lookup on page G3-3574](#).
- [Determining the translation table base address in the VMSAv8-32 translation regimes on page G3-3575](#).
- [Control of translation table walks on a TLB miss on page G3-3576](#).
- [Access to the Secure or Non-secure physical address map on page G3-3576](#).

See also [TLB maintenance requirements on page G3-3633](#).

### G3.4.1 Translation table walks for memory accesses using VMSAv8-32 translation regimes

A translation table walk occurs as the result of a TLB miss, and starts with a read of the appropriate starting-level translation table. The result of that read determines whether additional translation table reads are required, for this stage of translation, as described in either:

- [Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format on page G3-3584.](#)
- [Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G3-3603.](#)

---

———— **Note** —————

When using the Short-descriptor translation table format, the starting level for a translation table walk is always a first-level lookup. However, with the Long-descriptor translation table format, the starting-level can be either a first-level or a second-level lookup.

---

For the PL1&0 stage 1 translations, [SCTLR.EE](#) determines the endianness of the translation table lookups. [SCTLR](#) is Banked, and therefore the endianness is determined independently for each Security state.

[HSCTLR.EE](#) defines the endianness for the Non-secure PL2 stage 1 and Non-secure PL1&0 stage 2 translations.

---

———— **Note** —————

#### Dynamically changing translation table endianness

Because any change to [SCTLR.EE](#) or [HSCTLR.EE](#) requires synchronization before it is visible to subsequent operations, ARM strongly recommends that:

- [SCTLR.EE](#) is changed only when either:
  - Executing in a mode that does not use the translation tables affected by [SCTLR.EE](#).
  - Executing with [SCTLR.M](#) set to 0.
- [HSCTLR.EE](#) is changed only when either:
  - Executing in a mode that does not use the translation tables affected by [HSCTLR.EE](#).
  - Executing with [HSCTLR.M](#) set to 0.

---

The physical address of the base of the starting-level translation table is determined from the appropriate *Translation table base register* (TTBR), see [Determining the translation table base address in the VMSAv8-32 translation regimes on page G3-3575](#).

For more information, see [TLB maintenance operations and the memory order model on page G3-3635](#).

Translation table walks must access data or unified caches, or data and unified caches, of other agents participating in the coherency protocol, according to the shareability attributes described in the TTBR. These shareability attributes must be consistent with the shareability attributes for the translation tables themselves.

### G3.4.2 Information returned by a translation table lookup

When an associated stage of address translation is enabled, a memory access requires one or more translation table lookups. If the required translation table descriptor is not held in a TLB, a translation table walk is performed to obtain the descriptor. A lookup, whether from the TLB or as the result of a translation table walk, returns both:

- An output address that corresponds to the input address for the lookup.
- A set of properties that correspond to that output address.

The returned properties are classified as providing *address map control*, *access controls*, or *region attributes*. This classification determines how the descriptions of the properties are grouped. The classification is based on the following model:

#### Address map control

Memory accesses from Secure state can access either the Secure or the Non-secure address map, as summarized in [Access to the Secure or Non-secure physical address map on page G3-3576](#).

Memory accesses from Non-secure state can only access the Non-secure address map.

### Access controls

Determine whether the PE, in its current state, can access the output address that corresponds to the given input address. If not, a MMU fault is generated and there is no memory access.

*Memory access control* on page G3-3609 describes the properties in this group.

**Attributes** Are valid only for an output address that the PE, in its current state, can access. The attributes define aspects of the required behavior of accesses to the target memory region.

*Memory region attributes* on page G3-3618 describes the properties in this group.

## G3.4.3 Determining the translation table base address in the VMSAv8-32 translation regimes

On a TLB miss, the VMSA must perform a translation table walk, and therefore must find the base address of the translation table to use for its lookup. A TTBR holds this address. As [Figure G3-2 on page G3-3566](#) shows:

- For a Non-secure PL2 stage 1 translation, the **HTTBR** holds the required base address. The **HTCR** is the control register for these translations.
- For a Non-secure PL1&0 stage 2 translation, the **VTTBR** holds the required base address. The **VTCT** is the control register for these translations.
- For a PL1&0 stage 1 translation, either **TTBR0** or **TTBR1** holds the required base address. The **TTBCR** is the control register for these translations.

The Non-secure copies of **TTBR0**, **TTBR1**, and **TTBCR**, relate to the Non-secure PL1&0 stage 1 translation. The Secure copies of **TTBR0**, **TTBR1**, and **TTBCR**, relate to the Secure PL1&0 stage 1 translation.

For the PL1&0 translation table walks:

- **TTBR0** can be configured to describe the translation of VAs in the entire address map, or to describe only the translation of VAs in the lower part of the address map.
- If **TTBR0** is configured to describe the translation of VAs in the lower part of the address map, **TTBR1** is configured to describe the translation of VAs in the upper part of the address map.

The contents of the appropriate instance of the **TTBCR** determine whether the address map is separated into two parts, and where the separation occurs. The details of the separation depend on the current translation table format, see:

- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format* on page G3-3583.
- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format* on page G3-3598.

[Example G3-1](#) shows a typical use of the two sets of translation tables:

### Example G3-1 Example use of TTBR0 and TTBR1

An example of using the two TTBRs for PL1&0 stage 1 address translations is:

**TTBR0** Used for process-specific addresses.

Each process maintains a separate first-level translation table. On a context switch:

- **TTBR0** is updated to point to the first-level translation table for the new context.
- **TTBCR** is updated if this change changes the size of the translation table.
- The **CONTEXTIDR** is updated.

**TTBCR** can be programmed so that all translations use **TTBR0** in a manner compatible with architecture versions before ARMv6.

**TTBR1** Used for operating system and I/O addresses, that do not change on a context switch.

### G3.4.4 Control of translation table walks on a TLB miss

Two bits in the **TCR** for the translation stage required by a memory access control whether a translation table walk is performed on a TLB miss. These two bits are the:

- **PD0** and **PD1** bits, on a PE using the Short-descriptor translation table format.
- **EPD0** and **EPD1** bits, on a PE using the Long-descriptor translation table format.

———— **Note** ————

For the VMSAv8-32 translation regimes, the different bit names are because the bits are in different positions in **TTBCR**, depending on the translation table format.

The effect of these bits is:

**{E}PDx == 0** If a TLB miss occurs based on **TTBRx**, a translation table walk is performed. The current security state determines whether the memory access is Secure or Non-secure.

**{E}PDx == 1** If a TLB miss occurs based on **TTBRx**, a First level Translation fault is returned, and no translation table walk is performed.

### G3.4.5 Access to the Secure or Non-secure physical address map

As stated in *Address spaces in VMSAv8-32 on page G3-3564*, a PE can access independent Secure and Non-secure address maps. When the PL1 Exception level is using AArch32, these are defined by the translation tables identified by the Secure **TTBR0** and **TTBR1**. In both translation table formats in the Secure translation tables, the **NS** bit in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map:

**NS == 0** Access the Secure physical address space.

**NS == 1** Access the Non-secure physical address space.

———— **Note** ————

In the Non-secure translation tables, the corresponding bit is **SBZ**. Non-secure accesses always access the Non-secure physical address space, regardless of the value of this bit.

The Long-descriptor translation table format extends this control, adding an **NSTable** bit to the Secure translation tables, as described in *Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format on page G3-3597*. In the Non-secure translation tables, the corresponding bit is **SBZ**, and Non-secure accesses ignore the value of this bit.

The following sections describe the address map controls in the two implementations:

- *Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G3-3583.*
- *Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G3-3597.*

The following subsection gives more information.

### Secure and Non-secure address spaces

EL3 provides two physical address spaces, a Secure physical address space and a Non-secure physical address space.

As described in *Access to the Secure or Non-secure physical address map*, for the PL1&0 stage 1 translations when controlled from an Exception level using AArch32, the translation table base registers, **TTBR0**, **TTBR1**, and **TTBCR** are Banked between Secure and Non-secure versions, and the Security state of the PE when it performs a memory access selects the corresponding version of the registers. This means there are independent Secure and Non-secure versions of these translation tables, and translation table walks are made to the physical address space corresponding to the security state of the translation tables used.

For a translation table walk caused by a memory access from Non-secure state, all memory accesses are to the Non-secure address space.

For a translation table walk caused by a memory access from Secure state:

- When address translation is using the Long-descriptor translation table format:
    - The first lookup performed must access the Secure address space.
    - If a table descriptor read from the Secure address space has the NSTable bit set to 0, then the next level of lookup is from the Secure address space.
    - If a table descriptor read from the Secure address space has the NSTable bit set to 1, then the next level of lookup, and any subsequent level of lookup, is from the Non-secure address space.
- For more information, see [Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G3-3597](#).
- Otherwise, all memory accesses are to the Secure address space.

---

**Note**

- When executing in Non-secure state, additional translations are supported. For memory accesses from AArch32 state these are:
    - Non-secure PL2 stage 1 translation.
    - Non-secure PL1&0 stage 2 translation.These translations can access only the Non-secure address space.
  - A system implementation can alias parts of the Secure physical address space to the Non-secure physical address space in an implementation-specific way. As with any other aliasing of physical memory, the use of aliases in this way can require the use of cache maintenance operations to ensure that changes to memory made using one alias of the physical memory are visible to accesses to the other alias of the physical memory.
-

## G3.5 The VMSAv8-32 Short-descriptor translation table format

The Short-descriptor translation table format supports a memory map based on memory sections or pages:

**Supersections** Consist of 16MB blocks of memory. Support for Supersections is optional, except that an implementation that supports more than 32 bits of Physical Address must also support Supersections to provide access to the entire Physical Address space.

**Sections** Consist of 1MB blocks of memory.

**Large pages** Consist of 64KB blocks of memory.

**Small pages** Consist of 4KB blocks of memory.

Supersections, Sections and Large pages map large regions of memory using only a single TLB entry.

### ———— Note —————

Whether a VMSAv8-32 implementation of the Short-descriptor format translation tables supports supersections is IMPLEMENTATION DEFINED.

When using the Short-descriptor translation table format, two levels of translation tables are held in memory:

#### **First-level table**

Holds *first-level descriptors* that contain the base address and

- Translation properties for a Section and Supersection.
- Translation properties and pointers to a second-level table for a Large page or a Small page.

#### **Second-level tables**

Hold *second-level descriptors* that contain the base address and translation properties for a Small page or a Large page. With the Short-descriptor format, second-level tables can be referred to as *Page tables*.

A second-level table requires 1KByte of memory.

In the translation tables, in general, a descriptor is one of:

- An invalid or fault entry.
- A page table entry, that points to a next-level translation table.
- A page or section entry, that defines the memory properties for the access.
- A reserved format.

Bits[1:0] of the descriptor give the primary indication of the descriptor type.

[Figure G3-3 on page G3-3579](#) gives a general view of address translation when using the Short-descriptor translation table format.

**Figure G3-3 General view of address translation using Short-descriptor format translation tables**

*Additional requirements for Short-descriptor format translation tables on page G3-3582* describes why, when using the Short-descriptor format, Supersection and Large page entries must be repeated 16 times, as shown in *Figure G3-3*.

*VMSAv8-32 Short-descriptor translation table format descriptors, Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors on page G3-3582, and Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G3-3583* describe the format of the descriptors in the Short-descriptor format translation tables.

The following sections then describe the use of this translation table format:

- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format on page G3-3583.*
- *Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format on page G3-3584.*

### G3.5.1 VMSAv8-32 Short-descriptor translation table format descriptors

The following sections describe the formats of the entries in the Short-descriptor translation tables:

- *Short-descriptor translation table first-level descriptor formats.*
- *Short-descriptor translation table second-level descriptor formats on page G3-3581.*

For more information about second-level translation tables see *Additional requirements for Short-descriptor format translation tables on page G3-3582*.

#### ————— **Note** —————

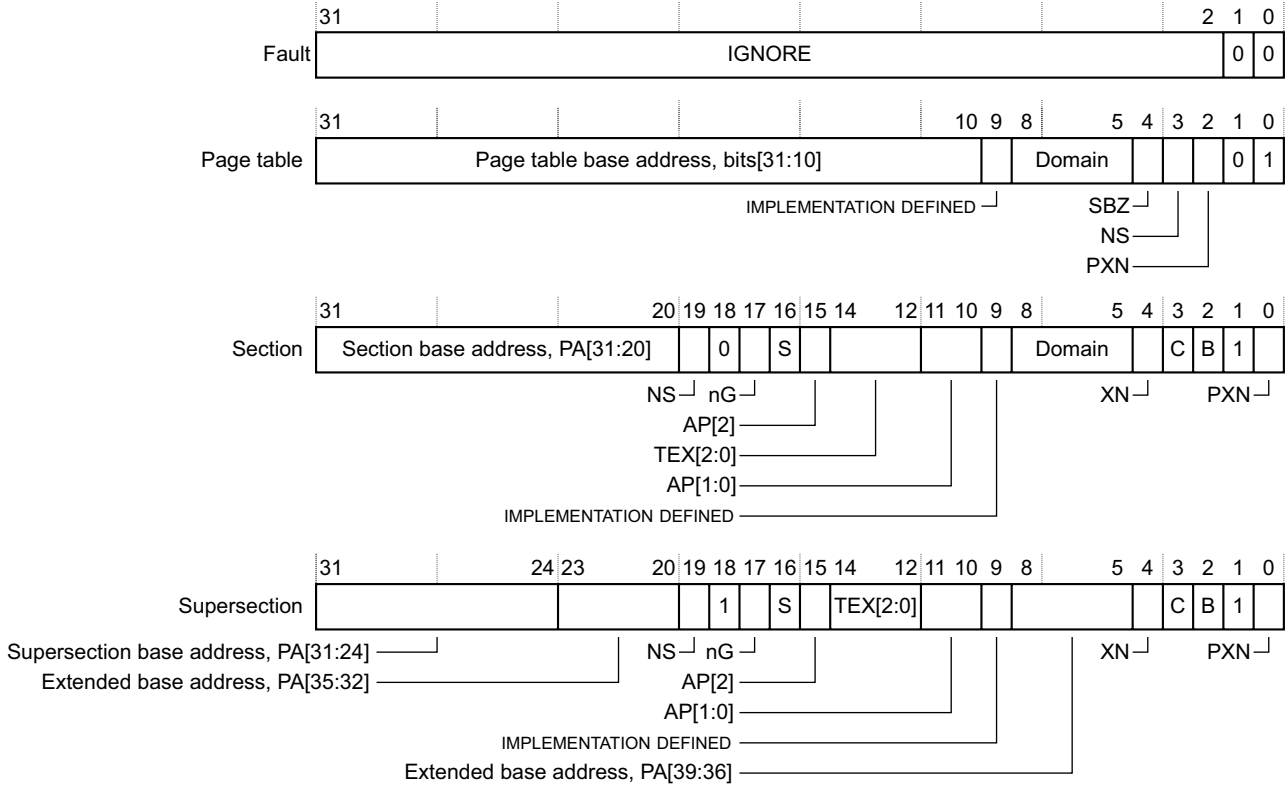

Previous versions of the *ARM Architecture Reference Manual*, and some other documentation, describes the AP[2] bit in the translation table entries as the APX bit.

*Information returned by a translation table lookup on page G3-3574* describes the classification of the non-address fields in the descriptors as address map control, access control, or attribute fields.

### Short-descriptor translation table first-level descriptor formats

Each entry in the first-level table describes the mapping of the associated 1MB VA range.

*Figure G3-4 on page G3-3580* shows the possible first-level descriptor formats.

**Figure G3-4 Short-descriptor first-level descriptor formats**

Descriptor bits[1:0] identify the descriptor type. The encoding of these bits is:

**0b00, Invalid or fault entry**

The associated VA is unmapped, and any attempt to access it generates a Translation fault.

Software can use bits[31:2] of the descriptor for its own purposes, because the hardware ignores these bits.

**0b01, Page table**

The descriptor gives the address of a second-level translation table, that specifies the mapping of the associated 1MByte VA range.

**0b10, Section or Supersection**

The descriptor gives the base address of the Section or Supersection. Bit[18] determines whether the entry describes a Section or a Supersection.

This encoding also defines the PXN bit as 0.

**0b11, Section or Supersection, if the implementation supports the PXN attribute**

This encoding is identical to 0b10, except that it defines the PXN bit as 1.

**Note**

A VMSAv8-32 implementation can use the Short-descriptor translation table format for the Secure EL3&0 or Non-secure EL1&0 stage 1 translations, by setting `TTCR.EAE` to 0.

The address information in the first-level descriptors is:

**Page table** Bits[31:10] of the descriptor are bits[31:10] of the address of a Page table.

**Section** Bits[31:20] of the descriptor are bits[31:20] of the address of the Section.

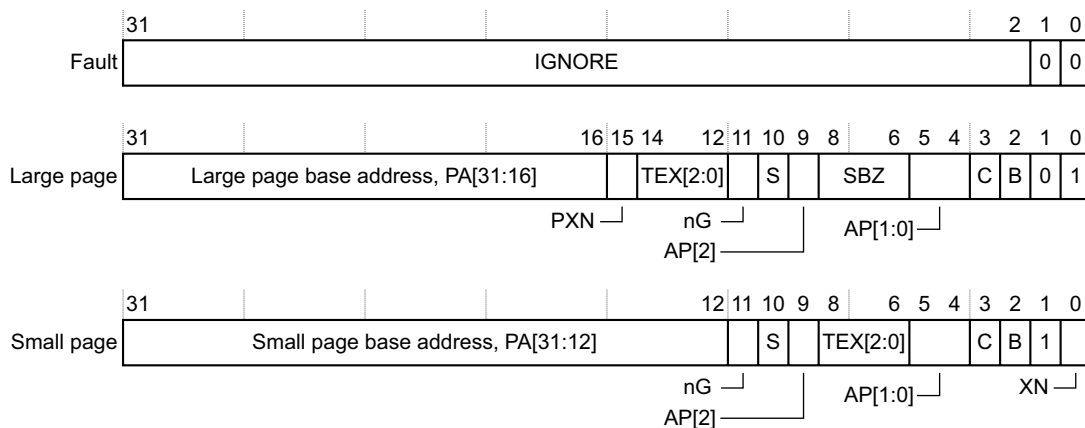

**Supersection** Bits[31:24] of the descriptor are bits[31:24] of the address of the Supersection.  
Optionally, bits[8:5, 23:20] of the descriptor are bits[39:32] of the extended Supersection address.

For the Non-secure EL1&0 translation tables, the address in the descriptor is the IPA of the Page table, Section, or Supersection. Otherwise, the address is the PA of the Page table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see *Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors* on page G3-3582.

### Short-descriptor translation table second-level descriptor formats

Figure G3-5 shows the possible formats of a second-level descriptor.

**Figure G3-5 Short-descriptor second-level descriptor formats**

Descriptor bits[1:0] identify the descriptor type. The encoding of these bits is:

**0b00, Invalid or fault entry**

The associated VA is unmapped, and attempting to access it generates a Translation fault.

Software can use bits[31:2] of the descriptor for its own purposes, because the hardware ignores these bits.

**0b01, Large page**

The descriptor gives the base address and properties of the Large page.

**0b1x, Small page**

The descriptor gives the base address and properties of the Small page.

In this descriptor format, bit[0] of the descriptor is the XN bit.

The address information in the second-level descriptors is:

**Large page** Bits[31:16] of the descriptor are bits[31:16] of the address of the Large page.

**Small page** Bits[31:12] of the descriptor are bits[31:12] of the address of the Small page.

For the Non-secure EL1&0 translation tables, the address in the descriptor is the IPA of the Page table, Section, or Supersection. Otherwise, the address is the PA of the Page table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see *Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors* on page G3-3582.

### Additional requirements for Short-descriptor format translation tables

When using Supersection or Large page descriptors in the Short-descriptor translation table format, the input address field that defines the Supersection or Large page descriptor address overlaps the table address field. In each case, the size of the overlap is 4 bits. The following diagrams show these overlaps:

- [Figure G3-8 on page G3-3587](#) for the first-level translation table Supersection entry.
- [Figure G3-10 on page G3-3589](#) for the second-level translation table Large page table entry.

Considering the case of using Large page table descriptors in a second-level translation table, this overlap means that for any specific Large page, the bottom four bits of the second-level translation table entry might take any value from 0b0000 to 0b1111. Therefore, each of these sixteen index values must point to a separate copy of the same descriptor.

This means that each Large page or Supersection descriptor must:

- Occur first on a sixteen-word boundary.
- Be repeated in 16 consecutive memory locations.

### G3.5.2 Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors

This section describes the descriptor fields other than the descriptor type field and the address field:

#### TEX[2:0], C, B

Memory region attribute bits, see [Memory region attributes on page G3-3618](#).

These bits are not present in a Page table entry.

#### XN bit

The Execute-never bit. Determines whether the PE can execute software from the addressed region, see [Execute-never restrictions on instruction fetching on page G3-3612](#).

This bit is not present in a Page table entry.

#### PXN bit

The Privileged execute-never bit. Determines whether the PE can execute software from the region when executing at PL1, see [Execute-never restrictions on instruction fetching on page G3-3612](#).

#### ———— Note —————

Memory accesses by software executing at EL2 always use the Long-descriptor translation table format.

When this bit is set to 1 in the Page table descriptor, it indicates that all memory pages described in the corresponding page table are Privileged execute-never.

#### NS bit

Non-secure bit. Specifies whether the translated PA is in the Secure or Non-secure address map, see [Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G3-3583](#).

This bit is not present in second-level descriptors. The value of the NS bit in the first level Page table descriptor applies to all entries in the corresponding second-level translation table.

#### Domain

Domain field, see [Domains, Short-descriptor format only on page G3-3614](#).

This field is not present in a Supersection entry. Memory described by Supersections is in domain 0.

This bit is not present in second-level descriptors. The value of the Domain field in the first level Page table descriptor applies to all entries in the corresponding second-level translation table.

#### An IMPLEMENTATION DEFINED bit

This bit is not present in second-level descriptors.

#### AP[2], AP[1:0]

Access Permissions bits, see [Memory access control on page G3-3609](#).

AP[0] can be configured as the *Access flag*, see [The Access flag on page G3-3615](#).

These bits are not present in a Page table entry.

**S bit** The Shareable bit. Determines whether the addressed region is Shareable memory, see [Memory region attributes](#) on page G3-3618.

This bit is not present in a Page table entry.

**nG bit** The not global bit. Determines how the translation is marked in the TLB, see [Global and process-specific translation table entries](#) on page G3-3630.

This bit is not present in a Page table entry.

**Bit[18], when bits[1:0] indicate a Section or Supersection descriptor**

**0** Descriptor is for a Section.

**1** Descriptor is for a Supersection.

### G3.5.3 Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format

[Access to the Secure or Non-secure physical address map](#) on page G3-3576 describes how the NS bit in the translation table entries:

- For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
- Is ignored by accesses from Non-secure state.

In the Short-descriptor translation table format, the NS bit is defined only in the first-level translation tables. This means that, in a first-level Page table descriptor, the NS bit defines the physical address space, Secure or Non-secure, for all of the Large pages and Small pages of memory described by that table.

The NS bit of a first-level Page table descriptor has no effect on the physical address space in which that translation table is held. As stated in [Secure and Non-secure address spaces](#) on page G3-3576, the physical address of that translation table is in:

- The Secure address space if the translation table walk is in Secure state.
- The Non-secure address space if the translation table walk is in Non-secure state.

This means the granularity of the Secure and Non-secure memory spaces is 1MB. However, in these memory spaces, table entries can define physical memory regions with a granularity of 4KB.

### G3.5.4 Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format

As described in [Determining the translation table base address in the VMSAv8-32 translation regimes](#) on page G3-3575, two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and **TTBR0** and **TTBR1** hold the base addresses for the two sets of tables. When using the Short-descriptor translation table format, the value of **TTBCR.N** indicates the number of most significant bits of the input VA that determine whether **TTBR0** or **TTBR1** holds the required translation table base address, as follows:

- If  $N == 0$  then use **TTBR0**. Setting **TTBCR.N** to zero disables use of a second set of translation tables.
- if  $N > 0$  then:
  - If bits[31:32-N] of the input VA are all zero then use **TTBR0**.
  - Otherwise use **TTBR1**.

[Table G3-4](#) shows how the value of N determines the lowest address translated using **TTBR1**, and the size of the first-level translation table addressed by **TTBR0**.

**Table G3-4 Effect of TTBCR.N on address translation, Short-descriptor format**

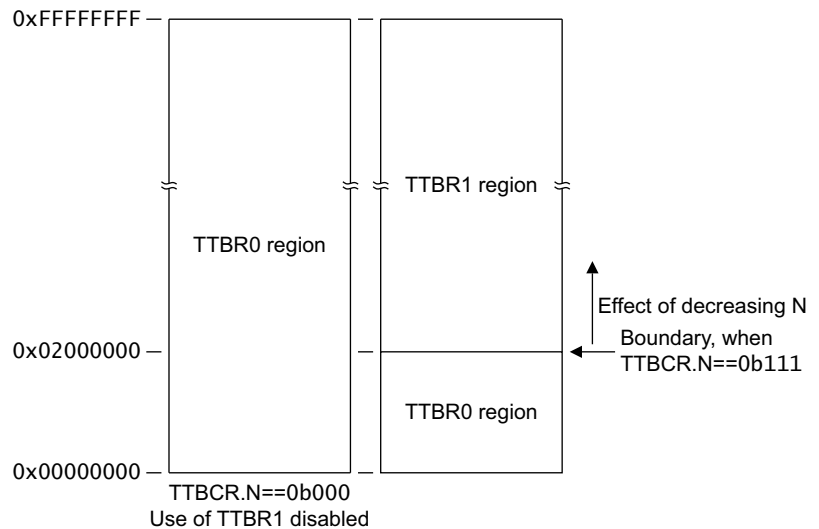

TTBCR.N	First address translated with TTBR1	TTBR0 table	
		Size	Index range
0b000	<b>TTBR1</b> not used	16KB	VA[31:20]
0b001	0x80000000	8KB	VA[30:20]
0b010	0x40000000	4KB	VA[29:20]

**Table G3-4 Effect of TTBCR.N on address translation, Short-descriptor format (continued)**

TTBCR.N	First address translated with TTBR1	TTBR0 table	
		Size	Index range
0b011	0x20000000	2KB	VA[28:20]
0b100	0x10000000	1KB	VA[27:20]
0b101	0x08000000	512 bytes	VA[26:20]
0b110	0x04000000	256 bytes	VA[25:20]
0b111	0x02000000	128 bytes	VA[24:20]

Whenever TTBCR.N is nonzero, the size of the translation table addressed by TTBR1 is 16KB.

Figure G3-6 shows how the value of TTBCR.N controls the boundary between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.

**Figure G3-6 How TTBCR.N controls the boundary between the TTBRs, Short-descriptor format**

In the selected TTBR, bits RGN, S and IRGN[1:0] define the memory region attributes for the translation table walk.

*Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format* describes the translation.

### G3.5.5 Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format

When using the Short-descriptor translation table format, and a memory access requires a translation table walk:

- A section-mapped access only requires a read of the first-level translation table.
- A page-mapped access also requires a read of the second-level translation table.

*Reading a first-level translation table on page G3-3585* describes how either TTBR1 or TTBR0 is used, with the accessed VA, to determine the address of the first-level descriptor.

*Reading a first-level translation table on page G3-3585* shows the output address as A[39:0]:

- For a Non-secure PL1&0 stage 1 translation, this is the IPA of the required descriptor. A Non-secure PL1&0 stage 2 translation of this address is performed to obtain the PA of the descriptor.
- Otherwise, this address is the PA of the required descriptor.

The full translation flow for Sections, Supersections, Small pages and Large pages then shows the complete translation flow for each valid memory access.

### Reading a first-level translation table

When performing a fetch based on **TTBR0**:

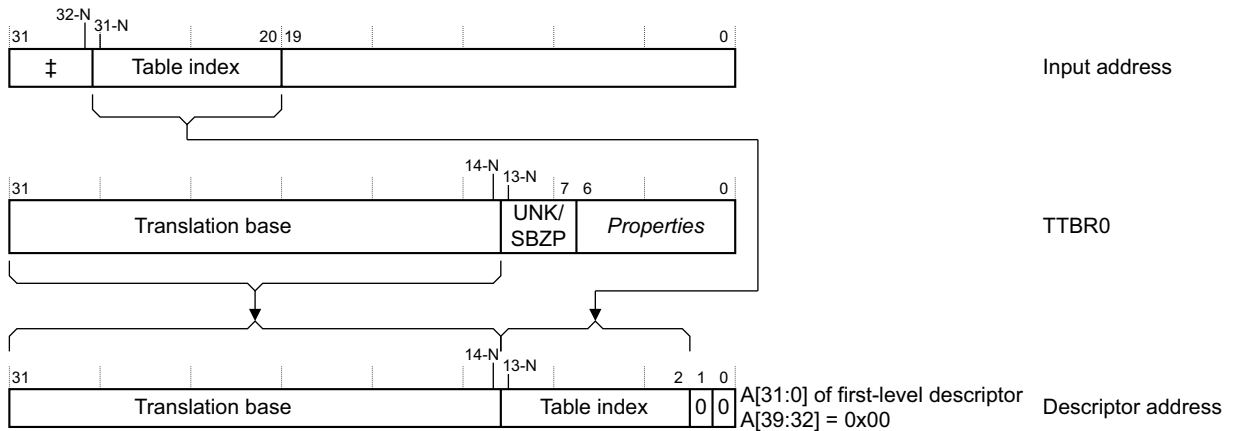

- The address bits taken from **TTBR0** vary between bits[31:14] and bits[31:7].
- The address bits taken from the VA, that is the input address for the translation, vary between bits[31:20] and bits[24:20].

The width of the **TTBR0** and VA fields depend on the value of **TTBCR.N**, as [Figure G3-7](#) shows.

When performing a fetch based on **TTBR1**, Bits **TTBR1**[31:14] are concatenated with bits[31:20] of the VA. This makes the fetch equivalent to that shown in [Figure G3-7](#), with  $N=0$ .

**Note**

See [The address and Properties fields shown in the translation flows on page G3-3586](#) for more information about the *Properties* label used in this and other figures.

‡ This field is absent if N is 0  
 N is the value of **TTBCR.N**  
 For details of the *Properties* field, see the register description

**Figure G3-7 Accessing first-level translation table based on TTBR0, Short-descriptor format**

Regardless of which register is used as the base for the fetch, the resulting output address selects a four-byte translation table entry that is one of:

- A first-level descriptor for a Section or Supersection.
- A *Page table* descriptor that points to a second-level translation table. In this case:
  - A second fetch is performed to retrieve a second-level descriptor.
  - The descriptor also contains some attributes for the access, see [Figure G3-4 on page G3-3580](#).
- A faulting entry.

### The full translation flow for Sections, Supersections, Small pages and Large pages

In a translation table walk, only the first lookup uses the translation table base address from the appropriate Translation table base register. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

This section summarizes how each of the memory section and page options is described in the translation tables, and has a subsection summarizing the full translation flow for each of the options.

As described in [VMSAv8-32 Short-descriptor translation table format descriptors](#) on page G3-3579, the four options are:

**Supersection** A 16MB memory region, see [Translation flow for a Supersection](#).

**Section** A 1MB memory region, see [Translation flow for a Section](#) on page G3-3587.

**Large page** A 64KB memory region, described by the combination of:

- A first-level translation table entry that indicates a second-level Page table address.
- A second-level descriptor that indicates a Large page.

See [Translation flow for a Large page](#) on page G3-3588.

**Small page** A 4KB memory region, described by the combination of:

- A first-level translation table entry that indicates a second-level Page table address.
- A second-level descriptor that indicates a Small page.

See [Translation flow for a Small page](#) on page G3-3590.

### ***The address and Properties fields shown in the translation flows***

For the Non-secure PL1&0 stage 1 translation tables:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the Section, Supersection, Large page, or Small page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

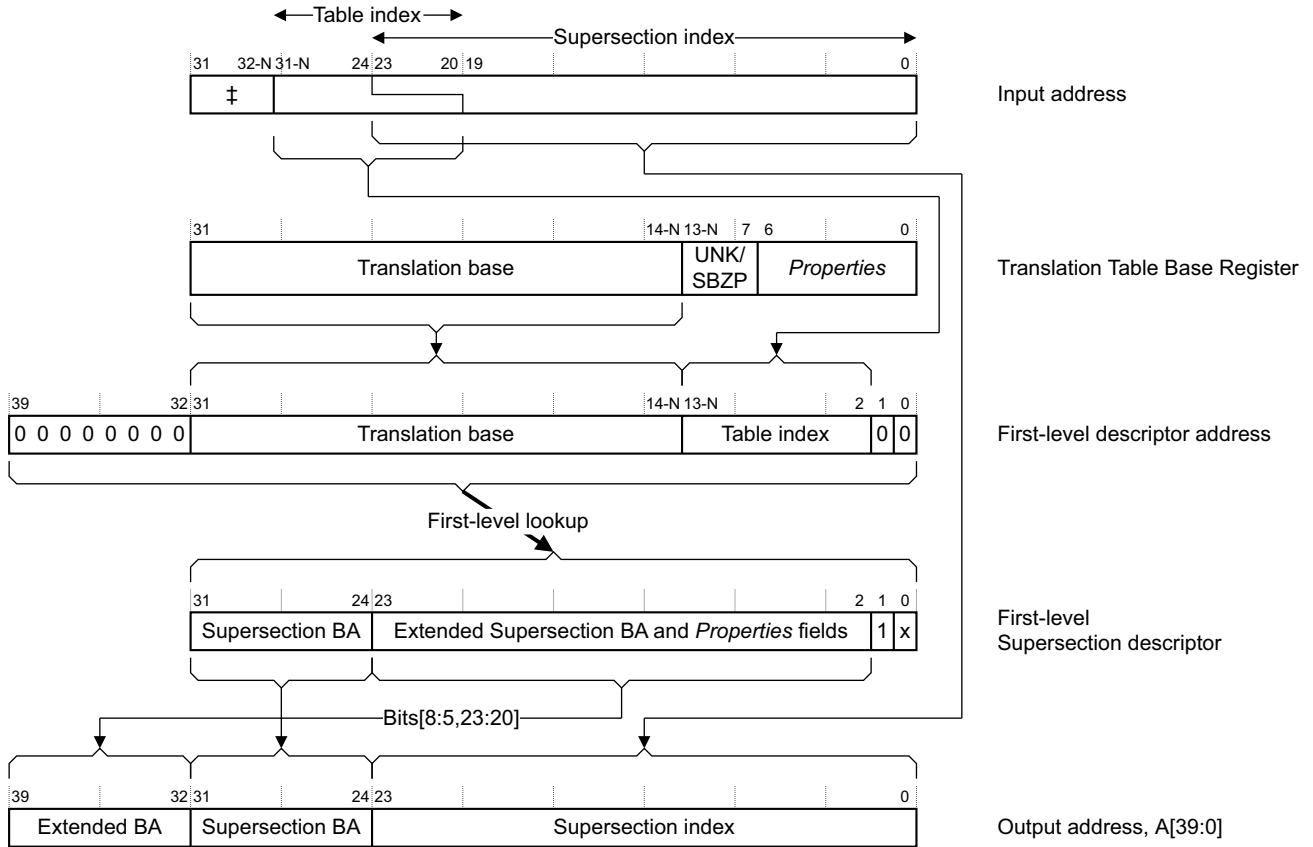

Otherwise, the address is the PA of the descriptor, Section, Supersection, Large page, or Small page.

*Properties* indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see [Information returned by a translation table lookup](#) on page G3-3574, and the description of the register or translation table descriptor.

For translations using the Short-descriptor translation table format, [VMSAv8-32 Short-descriptor translation table format descriptors](#) on page G3-3579 describes the descriptors formats.

### ***Translation flow for a Supersection***

[Figure G3-8](#) on page G3-3587 shows the complete translation flow for a Supersection. For more information about the fields shown in this figure see [The address and Properties fields shown in the translation flows](#).

‡ This field is absent if N is 0  
 BA = Base address  
 For a translation based on TTBR0, N is the value of TTBCR.N  
 For a translation based on TTBR1, N is 0  
 For details of *Properties* fields, see the register or descriptor description

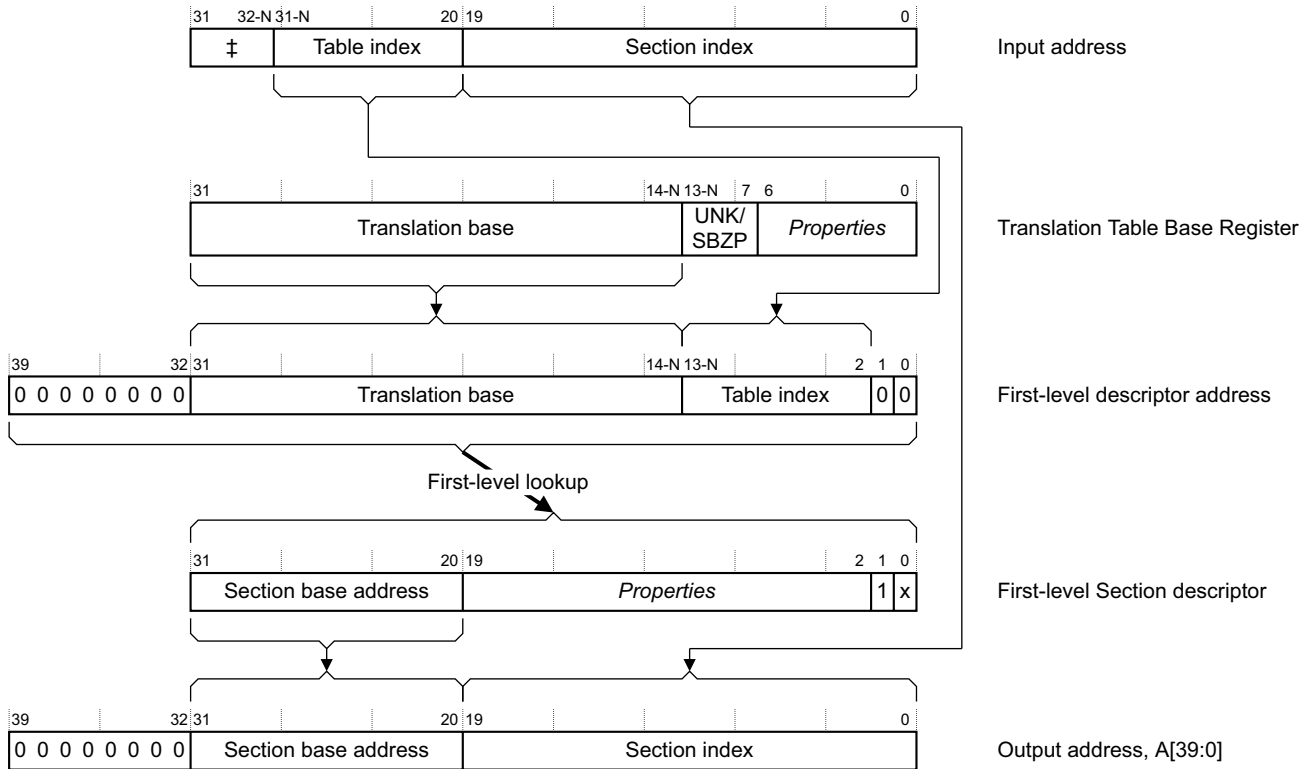

**Figure G3-8 VMSAv8-32 Short-descriptor Supersection address translation**

**Note**

Figure G3-8 shows how, when the input address, the VA, addresses a Supersection, the top four bits of the *Supersection index* bits of the address overlap the bottom four bits of the *Table index* bits. For more information, see [Additional requirements for Short-descriptor format translation tables](#) on page G3-3582.

**Translation flow for a Section**

Figure G3-9 on page G3-3588 shows the complete translation flow for a Section. For more information about the fields shown in this figure see [The address and Properties fields shown in the translation flows](#) on page G3-3586.

‡ This field is absent if N is 0  
 For a translation based on TTBR0, N is the value of TTBCR.N  
 For a translation based on TTBR1, N is 0  
 For details of *Properties* fields, see the register or descriptor description.

**Figure G3-9 VMSAv8-32 Short-descriptor Section address translation**

**Translation flow for a Large page**

Figure G3-10 on page G3-3589 shows the complete translation flow for a Large page. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows* on page G3-3586.

‡ This field is absent if N is 0  
 L1 = First-level, L2 = Second-level  
 For a translation based on TTBR0, N is the value of TTBCR.N  
 For a translation based on TTBR1, N is 0  
 For details of *Properties* fields, see the register or descriptor description

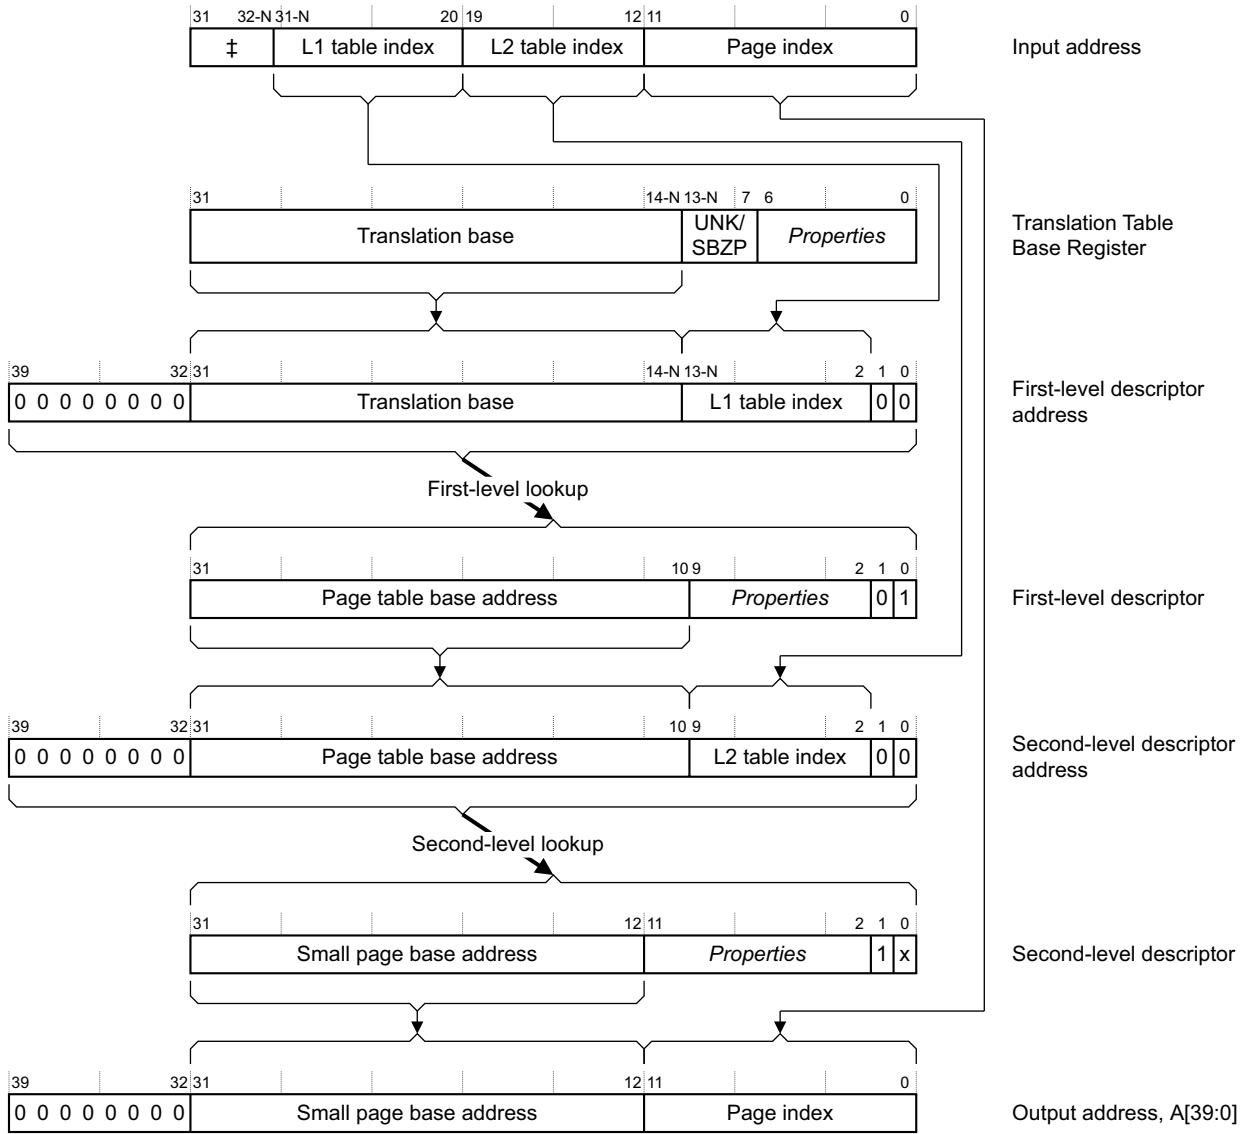

**Figure G3-10 VMSAv8-32 Short-descriptor Large page address translation**

**Note**

Figure G3-10 shows how, when the input address, the VA, addresses a Large page, the top four bits of the *page index* bits of the address overlap the bottom four bits of the *First-level table index* bits. For more information, see [Additional requirements for Short-descriptor format translation tables on page G3-3582](#).

**Translation flow for a Small page**

Figure G3-11 on page G3-3590 shows the complete translation flow for a Small page. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows* on page G3-3586.

‡ This field is absent if N is 0  
 L1 = First-level, L2 = Second-level  
 For a translation based on TTBR0, N is the value of TTBCR.N  
 For a translation based on TTBR1, N is 0  
 For details of *Properties* fields, see the register or descriptor description.

**Figure G3-11 VMSAv8-32 Short-descriptor Small page address translation**

## G3.6 The VMsAv8-32 Long-descriptor translation table format

The VMsAv8-32 Long-descriptor translation table format supports the assignment of memory attributes to memory *Pages*, at a granularity of 4KB, across the complete input address range. It also supports the assignment of memory attributes to *blocks* of memory, where a block can be 2MB or 1GB.

———— **Note** —————

- Although the VMsAv8-32 Long-descriptor format is limited to three levels of address lookup, its design and naming conventions support extension to additional levels, to support a larger input address range.
- Similarly, while the VMsAv8-32 implementation limits the output address range to 40 bits, its design supports extension to a larger output address range.

Figure G3-2 on page G3-3566 shows the different address translation stages. The Long-descriptor translation table format:

- Is used for:
  - The Non-secure PL2 stage 1 translation.
  - The Non-secure PL1&0 stage 2 translation.
- Can be used for the Secure and Non-secure PL1&0 translations.

When used for a stage 1 translation, the translation tables support an input address of up to 32 bits, corresponding to the VA address range of the PE.

When used for a stage 2 translation, the translation tables support an input address range of up to 40 bits, to support the translation from IPA to PA. If the input address for the stage 2 translation is a 32-bit address then this address is zero-extended to 40 bits.

———— **Note** —————

When the Short-descriptor translation table format is used for the Non-secure stage 1 translations, this generates 32-bit IPAs. These are zero-extended to 40 bits to provide the input address for the stage 2 translation.

*Overview of VMsAv8-32 address translation using Long-descriptor translation tables* summarizes address translation from AArch32 state when using the Long-descriptor format translation tables.

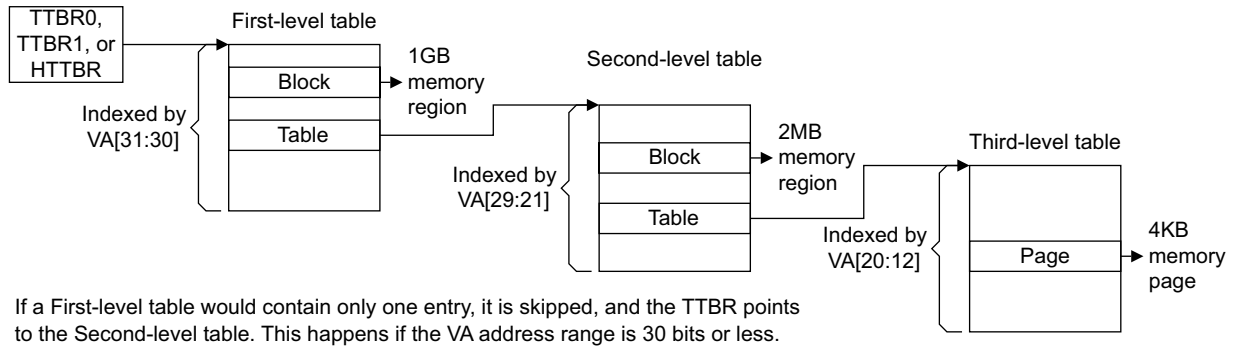

*VMsAv8-32 Long-descriptor translation table format descriptors* on page G3-3592, *Memory attributes in the VMsAv8-32 Long-descriptor translation table format descriptors* on page G3-3595, and *Control of Secure or Non-secure memory access, VMsAv8-32 Long-descriptor format* on page G3-3597 describe the format of the descriptors in the Long-descriptor format translation tables.

The following sections then describe the use of this translation table format:

- *Selecting between TTBR0 and TTBR1, VMsAv8-32 Long-descriptor translation table format* on page G3-3598.
- *VMsAv8-32 Long-descriptor translation table format address lookup levels* on page G3-3600.
- *Translation table walks, when using the VMsAv8-32 Long-descriptor translation table format* on page G3-3603.

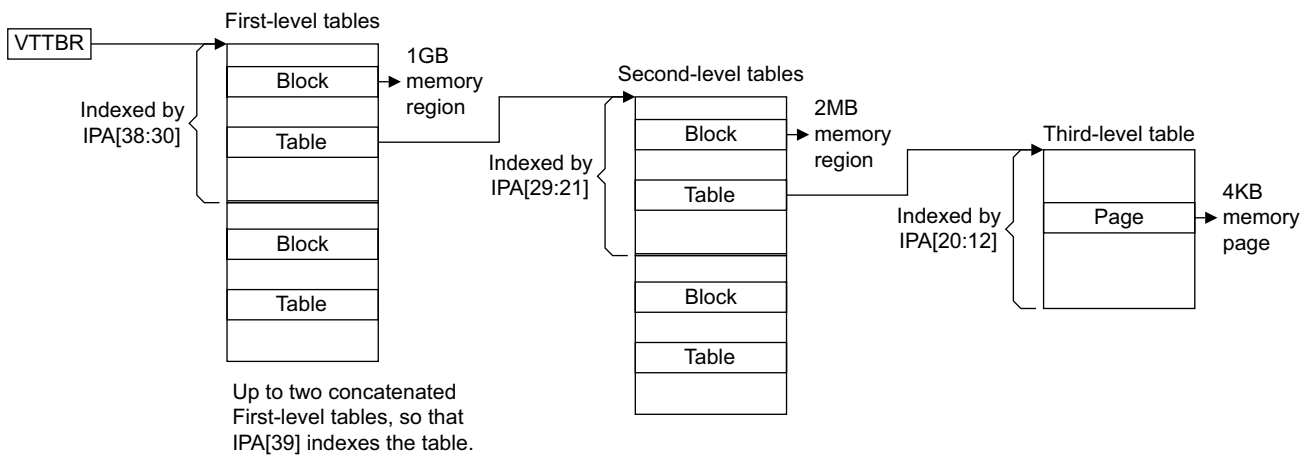

### G3.6.1 Overview of VMsAv8-32 address translation using Long-descriptor translation tables

Figure G3-12 on page G3-3592 gives a general view of VMsAv8-32 stage 1 address translation when using the Long-descriptor translation table format.

**Figure G3-12** General view of VMSAv8-32 stage 1 address translation using Long-descriptor format

Figure G3-13 gives a general view of VMSAv8-32 stage 2 address translation. Stage 2 translation always uses the Long-descriptor translation table format.

If a First-level table would contain 16 entries or fewer, first-level lookup can be omitted. If so, VTTBR points to the start of a block of concatenated Second-level tables. See text for more information.

**Figure G3-13** General view of VMSAv8-32 stage 2 address translation, Long-descriptor translation table format

*Use of concatenated translation tables for stage 2 translations* on page G3-3601 describes how using concatenated Second-level tables means lookup can start at the Second level, as referred to in Figure G3-13.

### G3.6.2 VMSAv8-32 Long-descriptor translation table format descriptors

As described in *VMSAv8-32 Long-descriptor translation table format address lookup levels* on page G3-3600, the Long-descriptor translation table format provides up to three levels of address lookup. A translation table walk starts either at the first level or the second level of address lookup.

In general, a descriptor is one of:

- An invalid or fault entry.
- A table entry, that points to the next-level translation table.
- A block entry, that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.

The following sections describe the Long-descriptor translation table descriptor formats:

- *VMSAv8-32 Long-descriptor first-level and second-level descriptor formats* on page G3-3593.
- *VMSAv8-32 Long-descriptor translation table third-level descriptor formats* on page G3-3594.

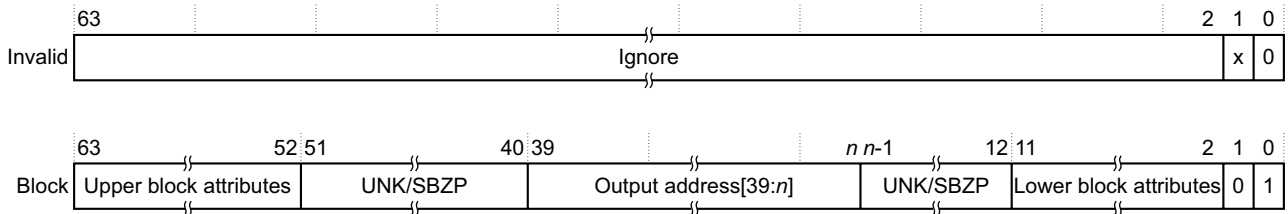

Information returned by a translation table lookup on page G3-3574 describes the classification of the non-address fields in the descriptors between *address map control*, *access controls*, and *region attributes*.

### VMSAv8-32 Long-descriptor first-level and second-level descriptor formats

In the Long-descriptor translation tables, the formats of the first-level and second-level descriptors differ only in the size of the block of memory addressed by the block descriptor. A block entry:

- In a first-level table describes the mapping of the associated 1GB input address range.
- In a second-level table describes the mapping of the associated 2MB input address range.

Figure G3-14 shows the Long-descriptor first-level and second-level descriptor formats:

For the first-level descriptor, n is 30. For the second-level descriptor, n is 21.

The first-level descriptor returns the address of the second-level table.  
 The second-level descriptor returns the address of the third-level table.

Figure G3-14 VMSAv8-32 Long-descriptor first-level and second-level descriptor formats

#### Descriptor encodings, Long-descriptor first-level and second-level formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

- 0, Block** The descriptor gives the base address of a block of memory, and the attributes for that memory region.
- 1, Table** The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

The other fields in the valid descriptors are:

#### Block descriptor

Gives the base address and attributes of a block of memory:

- For a first-level Block descriptor, bits[47:30] are bits[47:30] of the output address that specifies a 1GB block of memory.
- For a second-level Block descriptor, bits[47:21] are bits[47:21] of the output address that specifies a 2MB block of memory.

Bits[63:52, 11:2] provide attributes for the target memory block, see [Memory attributes in the VMSAv8-32 Long-descriptor translation table format descriptors on page G3-3595](#). The position and contents of these bits are identical in the second-level block descriptor and in the third-level page descriptor.

**Table descriptor**

Bits[47:m] are bits[47:m] of the address of the required next-level table. Bits[m-1:0] of the table address are zero:

- For a first-level Table descriptor, this is the address of a second-level table.
- For a second-level Table descriptor, this is the address of a third-level table.

For a stage 1 translation only, bits[63:59] provide attributes for the next-level lookup, see [Memory attributes in the VMSAv8-32 Long-descriptor translation table format descriptors on page G3-3595](#).

If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target block or table. Otherwise, it is the PA of the target block or table.

**VMSAv8-32 Long-descriptor translation table third-level descriptor formats**

Each entry in a third-level table describes the mapping of the associated 4KB input address range.

Figure G3-15 shows the Long-descriptor third-level descriptor formats.

**Figure G3-15 VMSAv8-32 Long-descriptor third-level descriptor formats**

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

**0, Reserved, invalid**

Behaves identically to encodings with bit[0] set to 0.

This encoding must not be used in third-level translation tables.

**1, Page** Gives the address and attributes of a 4KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

**Page descriptor**

Bits[47:12] are bits[47:12] of the output address for a page of memory.

Bits[63:52, 11:2] provide attributes for the target memory page, see [Memory attributes in the VMSAv8-32 Long-descriptor translation table format descriptors on page G3-3595](#). The position and contents of these bits are identical in the first-level block descriptor and in the second-level block descriptor.

If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target page. Otherwise, it is the PA of the target page.

### G3.6.3 Memory attributes in the VMSAv8-32 Long-descriptor translation table format descriptors

The memory attributes in the VMSAv8-32 Long-descriptor translation tables are based on those in the Short-descriptor translation table format, with some extensions. *Memory region attributes* on page G3-3618 describes these attributes. In the Long-descriptor translation table format:

- Table entries for stage 1 translations define attributes for the next level of lookup, see *Next-level attributes in VMSAv8-32 Long-descriptor stage 1 Table descriptors*
- Block and Page entries define memory attributes for the target block or page of memory. Stage 1 and stage 2 translations have some differences in these attributes, see:
  - *Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors.*
  - *Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors* on page G3-3596.

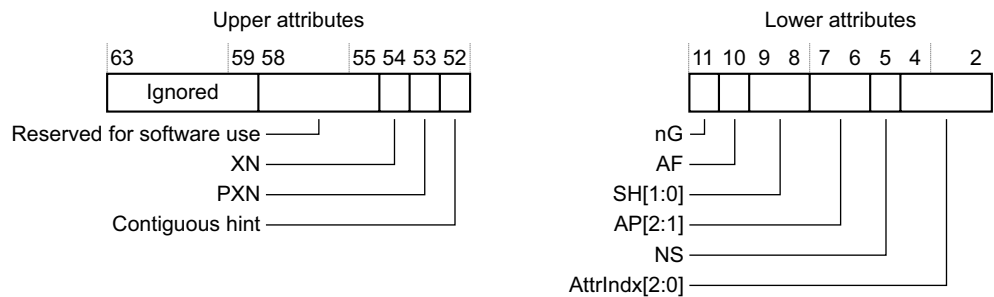

#### Next-level attributes in VMSAv8-32 Long-descriptor stage 1 Table descriptors

In a Table descriptor for a stage 1 translation, bits[63:59] of the descriptor define the following attributes for the next-level translation table access:

- NSTable, bit[63]** For memory accesses from Secure state, specifies the security level for subsequent levels of lookup, see *Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format* on page G3-3597.  
 For memory accesses from Non-secure state, this bit is ignored.
- APTable, bits[62:61]** Access permissions limit for subsequent levels of lookup, see *Hierarchical control of access permissions, Long-descriptor format* on page G3-3610.  
 APTable[0] is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.
- XNTable, bit[60]** XN limit for subsequent levels of lookup, see *Hierarchical control of instruction fetching, Long-descriptor format* on page G3-3613.
- PXNTable, bit[59]** PXN limit for subsequent levels of lookup, see *Hierarchical control of instruction fetching, Long-descriptor format* on page G3-3613.  
 This bit is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.

#### Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors

Block and Page descriptors split the memory attributes into an upper block and a lower block. Figure G3-16 shows the memory attribute fields in these blocks, for a stage 1 translation:

**Figure G3-16 VMSAv8-32 memory attribute fields in Long-descriptor stage 1 Block and Page descriptors**

For a stage 1 descriptor, the attributes are:

- XN, bit[54]** The Execute-never bit. Determines whether the region is executable, see *Execute-never restrictions on instruction fetching* on page G3-3612.
- PXN, bit[53]** The Privileged execute-never bit. Determines whether the region is executable at EL1, see *Execute-never restrictions on instruction fetching* on page G3-3612.

This bit is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.

**Contiguous, bit[52]**

Indicates that 16 adjacent translation table entries point to contiguous memory regions, see [Contiguous bit on page G3-3625](#).

**nG, bit[11]**

The not global bit. Determines how the translation is marked in the TLB, see [Global and process-specific translation table entries on page G3-3630](#).

This bit is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.

**AF, bit[10]**

The Access flag, see [The Access flag on page G3-3615](#).

**SH, bits[9:8]**

Shareability field, see [Memory region attributes on page G3-3618](#).

**AP[2:1], bits[7:6]**

Access Permissions bits, see [Memory access control on page G3-3609](#).

———— **Note** ————

For consistency with the Short-descriptor translation table formats, the Long-descriptor format defines AP[2:1] as the Access Permissions bits, and does not define an AP[0] bit.

AP[1] is reserved, SBO, in the Non-secure PL2 stage 1 translation tables.

**NS, bit[5]**

Non-secure bit. For memory accesses from Secure state, specifies whether the output address is in Secure or Non-secure memory, see [Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G3-3597](#).

For memory accesses from Non-secure state, this bit is ignored.

**AttrIndx[2:0], bits[4:2]**

Stage 1 memory attributes index field, for the indicated Memory Attribute Indirection Register, see [VMSAv8-32 Long-descriptor format memory region attributes on page G3-3624](#).

In the upper attributes block, the architecture guarantees that hardware does not alter the fields marked as *Ignored* and *Reserved for software use*. For more information see [Other fields in the Long-descriptor translation table format descriptors on page G3-3625](#).

**Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors**

Block and Page descriptors split the memory attributes into an upper block and a lower block. [Figure G3-17](#) shows the memory attribute fields in these blocks, for a stage 2 translation:

**Figure G3-17 VMSAv8-32 memory attribute fields in Long-descriptor stage 2 Block and Page descriptors**

For a stage 2 descriptor, the attributes are:

**XN, bit[54]**

The Execute-never bit. Determines whether the region is executable, see [Execute-never restrictions on instruction fetching on page G3-3612](#).

**Contiguous, bit[52]**

Indicates that 16 adjacent translation table entries point to contiguous memory regions, see [Contiguous bit on page G3-3625](#).

**AF, bit[10]** The Access flag, see *The Access flag* on page G3-3615.

**SH, bits[9:8]** Shareability field, see *EL2 control of Non-secure memory region attributes* on page G3-3625.

**S2AP, bits[7:6]**

Stage 2 Access Permissions bits, see *Hyp mode control of Non-secure access permissions* on page G3-3616.

———— **Note** —————

In the original VMSAv7-32 Long-descriptor attribute definition, this field was called HAP[2:1], for consistency with the AP[2:1] field in the stage 1 descriptors and despite there being no HAP[0] bit. ARMv8 renames the field for greater clarity.

**MemAttr, bits[5:2]**

Stage 2 memory attributes, see *EL2 control of Non-secure memory region attributes* on page G3-3625.

In the upper attributes block:

- The field marked as *Reserved for System MMU use* is ignored by the PE. The architecture guarantees that the PE does not alter this field.
- The architecture guarantees that the PE does not alter the fields marked as *Ignored* and *Reserved for software use*.

For more information see *Other fields in the Long-descriptor translation table format descriptors* on page G3-3625.

## G3.6.4 Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format

*Access to the Secure or Non-secure physical address map* on page G3-3576 describes how the NS bit in the translation table entries:

- For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
- Is ignored by accesses from Non-secure state.

In the Long-descriptor format:

- The NS bit relates only to the memory block or page at the output address defined by the descriptor.
- The descriptors also include an NSTable bit, see *Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format*.

The NS and NSTable bits are valid only for memory accesses from Secure state. Memory accesses from Non-secure state ignore the values of these bits.

### Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format

For Long-descriptor format table descriptors for stage 1 translations, the descriptor includes an NSTable bit, that indicates whether the table identified in the descriptor is in Secure or Non-secure memory. For accesses from Secure state, the meaning of the NSTable bit is:

**NSTable == 0** The defined table address is in the Secure physical address space. In the descriptors in that translation table, NS bits and NSTable bits have their defined meanings.

**NSTable == 1** The defined table address is in the Non-secure physical address space. Because this table is fetched from the Non-secure address space, the NS and NSTable bits in the descriptors in this table must be ignored. This means that, for this table:

- The value of the NS bit in any block or page descriptor is ignored. The block or page address is refers to Non-secure memory.

- The value of the NSTable bit in any table descriptor is ignored, and the table address refers to Non-secure memory. When this table is accessed, the NS bit in any block or page descriptor is ignored, and all descriptors in the table refer to Non-secure memory.

In addition, an entry fetched in Secure state is treated as non-global if either:

- NSTable is set to 1.
- The fetch ignores the values of NS and NSTable, because of a higher-level fetch with NSTable set to 1.

That is, these entries must be treated as if nG==1, regardless of the value of the nG bit. For more information about the nG bit, see [Global and process-specific translation table entries on page G3-3630](#).

———— **Note** —————

- When using the Long-descriptor format, table descriptors are defined only for the first level and second level of lookup.
- Stage 2 translations are performed only for operations in Non-secure state, that can access only the Non-secure address space. Therefore, the stage 2 descriptors do not include NS or NSTable bits.

### G3.6.5 Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format

As described in [Determining the translation table base address in the VMSAv8-32 translation regimes on page G3-3575](#), two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and **TTBR0** and **TTBR1** hold the base addresses for the two sets of tables. The Long-descriptor translation table format provides more flexibility in defining the boundary between using **TTBR0** and using **TTBR1**. When a PL1&0 stage 1 address translation is enabled, **TTBR0** is always used. If **TTBR1** is also used then:

- **TTBR1** is used for the top part of the input address range.
- **TTBR0** is used for the bottom part of the input address range.

The **TTBCR.T0SZ** and **TTBCR.T1SZ** size fields control the use of **TTBR0** and **TTBR1**, as [Table G3-5](#) shows.

**Table G3-5 Use of TTBR0 and TTBR1, Long-descriptor format**

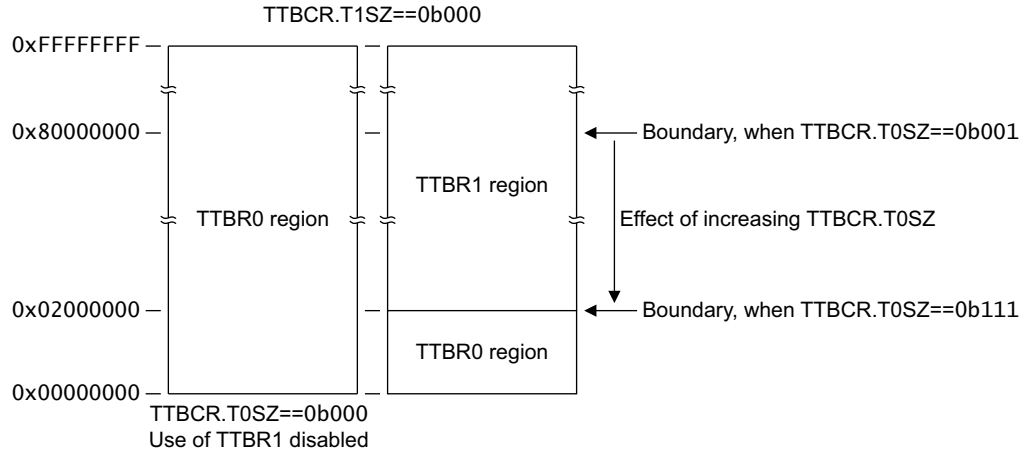

TTBCR		Input address range using:	
T0SZ	T1SZ	TTBR0	TTBR1
0b000	0b000	All addresses	Not used
$M^a$	0b000	Zero to $(2^{(32-M)}-1)$	$2^{32-M}$ to maximum input address
0b000	$N^a$	Zero to $(2^{32-2^{(32-N)}}-1)$	$2^{32-2^{(32-N)}}$ to maximum input address
$M^a$	$N^a$	Zero to $(2^{(32-M)}-1)$	$2^{32-2^{(32-N)}}$ to maximum input address

a.  $M, N$  must be greater than 0. The maximum possible value for each of T0SZ and T1SZ is 7.

For stage 1 translations, the input address is always a VA, and the maximum possible VA is  $(2^{32}-1)$ .

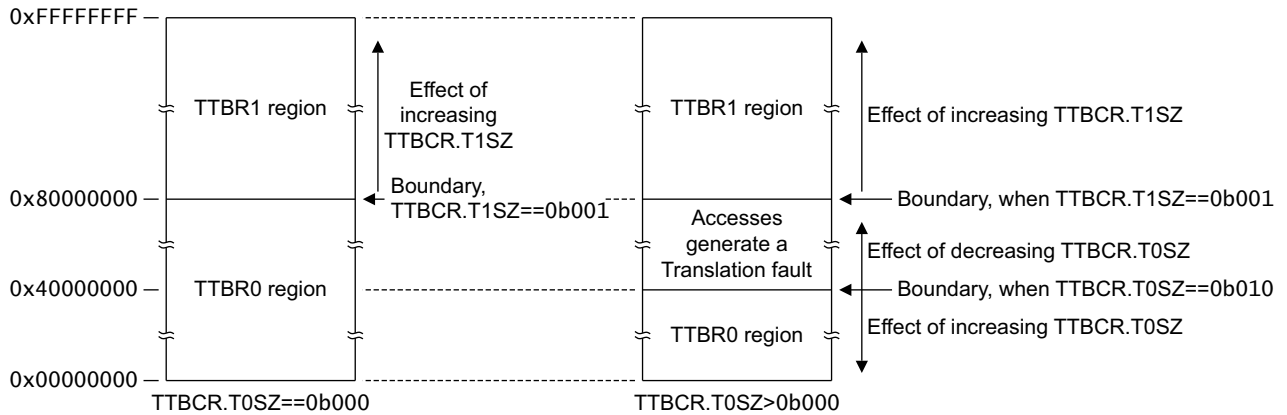

When address translation is using the Long-descriptor translation table format:

- [Figure G3-18 on page G3-3599](#) shows how, when **TTBCR.T1SZ** is zero, the value of **TTBCR.T0SZ** controls the boundary between VAs that are translated using **TTBR0**, and VAs that are translated using **TTBR1**.

**Figure G3-18 Control of TTBR boundary, when TTBCR.T1SZ is zero**

- [Figure G3-19](#) shows how, when **TTBCR.T1SZ** is nonzero, the values of **TTBCR.T0SZ** and **TTBCR.T1SZ** control the boundaries between VAs that are translated using **TTBR0**, and VAs that are translated using **TTBR1**.

**Figure G3-19 Control of TTBR boundaries, when TTBCR.T1SZ is nonzero**

When **T0SZ** and **T1SZ** are both nonzero:

- If both fields are set to **0b001**, the boundary between the two regions is **0x80000000**. This is identical to having **T0SZ** set to **0b000** and **T1SZ** set to **0b001**.
- Otherwise, the **TTBR0** and **TTBR1** regions are non-contiguous. In this case, any attempt to access an address that is in that gap between the **TTBR0** and **TTBR1** regions generates a Translation fault.

When using the Long-descriptor translation table format:

- The **TTBCR** contains fields that define memory region attributes for the translation table walk, for each TTBR. These are the **SH0**, **ORGN0**, **IRGN0**, **SH1**, **ORGN1**, and **IRGN1** bits.
- **TTBR0** and **TTBR1** each contain an **ASID** field, and the **TTBCR.A1** field selects which **ASID** to use.

For this translation table format, [VMSAv8-32 Long-descriptor translation table format address lookup levels](#) on page G3-3600 summarizes the lookup levels, and [Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format](#) on page G3-3603 describes the possible translations.

### Possible translation table registers programming errors

In all the descriptions in this subsection, the *size of the input address* supported for a PL1&0 stage 1 translation refers to the size specified by a **TTBCR.TxSZ** field.

---

**Note**

---

For a PL1&0 stage 1 translation, this section has described how the input address range can be split so that the lower addresses are translated by **TTBR0** and the higher addresses are translated by **TTBR1**. In this case, each of input address sizes specified by **TTBCR**.{T0SZ, T1SZ} is smaller than the total address size supported by the stage of translation.

The following are possible errors in the programming of **TTBR0**, **TTBR1**, and **TTBCR**. For the translation of a particular address at a particular stage of translation, either:

- The block size being used to translate the address is larger than the size of the input address supported at a stage of translation used in performing the required translation. This can occur only for the PL1&0 stage 1 translations, and only when either **TTBCR**.T0SZ or **TTBCR**.T1SZ is zero, meaning there is no gap between the address range translated by **TTBR0** and the range translated by **TTBR1**. In this case, this programming error occurs if a block translated from the region that has TxSZ set to zero straddles the boundary between the two address ranges. [Example G3-2](#) shows an example of this mis-programming.
- The address range translated by a set of blocks marked as contiguous, by use of the contiguous bit, is larger than the size of the input address supported at a stage of translation used in performing the required translation.

### Example G3-2 Translation table programming error

---

If **TTBCR**.T0SZ is programmed to 0 and **TTBCR**.T1SZ is programmed to 7, this means:

- **TTBR0** translates addresses in the range 0x00000000-0xFDFFFFFF.
- **TTBR1** translates addresses in the range 0xFE000000-0xFFFFFFFF.

The translation table indicated by **TTBR0** might be programmed with a block entry for a 1GB region starting at 0xC0000000. This covers the address range 0xC0000000-0xFFFFFFFF, that overlaps the **TTBR1** address range. This means this block size is larger than the input address size supported for translations using **TTBR0**, and therefore this is a programming error.

To understand why this must be a programming error, consider a memory access to address 0xFFFF0000. According to the **TTBCR**.{T0SZ, T1SZ} values, this must be translated using **TTBR1**. However, the access matches a TLB entry for the translation, using **TTBR0**, of the block at 0xC0000000. Hardware is not required to detect that the access to 0xFFFF0000 is being translated incorrectly.

---

In these cases, an implementation might use one of the following approaches:

- Treat such a block, that might be a block within a contiguous set of blocks, as causing a Translation fault, even though the block is valid, and the address accessed within that block is within the size of the input address supported at a stage of translation.
- Treat such a block, that might be a block within a contiguous set of blocks, as not causing a Translation fault, even though the address accessed within that block is outside the size of the input address supported at a stage of translation, provided that both of the following apply:
  - The block is valid.
  - At least one address within the block, or contiguous set of blocks, is within the size of the input address supported at a stage of translation.

## G3.6.6 VMSAv8-32 Long-descriptor translation table format address lookup levels

As stated at the start of this section, because the Long-descriptor translation table format is used for the Non-secure PL1&0 stage 2 translations, the format must support input addresses of up to 40 bits.

Table G3-6 summarizes the properties of the different levels of address lookup when using this format.

**Table G3-6 Properties of the three levels of address lookup with VMSAv8-32 Long-descriptor translation tables**

Level	Input address		Output address <sup>a</sup>		Number of entries
	Size	Address range <sup>b</sup>	Size	Address range	
First	Up to 512GB	Up to Address[38:0]	1GB	Address[39:30]	Up to 512
Second	Up to 1GB	Up to Address[29:0]	2MB	Address[39:21]	Up to 512
Third	2MB	Address[20:0]	4KB	Address[47:12]	512

- a. Output address when an entry addresses a block of memory or a memory page. If an entry addresses the next level of address lookup it specifies Address[39:12] for the next-level translation table.
- b. Input address range for the translation table. See *Use of concatenated first-level translation tables* on page G3-3602 for details of support for additional bits of address at a given level, including possible support of a 40-bit input address range at the first level.

For first-level and second-level tables, reducing the input address range reduces the number of addresses in the table and therefore reduces the table size. The appropriate Translation Table Control Register specifies the input address range.

Stage 1 translations require an input address range of up to 32 bits, corresponding to VA[31:0]. For these translations:

- For a memory access from a mode other than Hyp mode, the Secure or Non-secure **TTBR0** or **TTBR1** holds the translation table base address, and the Secure or Non-secure **TTBCR** is the control register.
- For a memory access from Hyp mode, **HTTBR** holds the translation table base address, and **HTCR** is the control register.

———— **Note** —————

For translations controlled by **TTBR0** and **TTBR1**, if neither Translation Table Base Register has an input address range larger than 1GB, then translation starts at the second level. Together, **TTBR0** and **TTBR1** can still cover the 32-bit VA input address range.

Stage 2 translations require an input address range of up to 40 bits, corresponding to IPA[39:0], and the supported input address size is configurable in the range 25-40 bits. Table G3-6 indicates a requirement for the translation mechanism to support a 39-bit input address range, Address[38:0]. *Use of concatenated translation tables for stage 2 translations* describes how a 40-bit IPA address range is supported. For stage 2 translations:

- **VTTBR** holds the translation table base address, and **VTTCR** is the control register.
- If a supplied input address is larger than the configured input address size, a Translation fault is generated.

**Use of concatenated translation tables for stage 2 translations**

If a stage 2 translation requires 16 entries or fewer in its top-level translation table, it can instead:

- Require the corresponding number of concatenated translation tables at the next translation level, aligned to the size of the block of concatenated translation tables.
- Start the translation at that next translation level.

———— **Note** —————

Stage 2 translations always use the Long-descriptor translation table format.

Use of this translation scheme is:

- Required when the stage 2 translation supports a 40-bit input address range, see [Use of concatenated first-level translation tables](#).
- Supported for a stage 2 translation with an input address range of 31-34 bits, see [Use of concatenated second-level translation tables](#).

———— **Note** —————

This translation scheme:

- Avoids the overhead of an additional level of translation
- Requires the software that is defining the translation to:
  - Define the concatenated translation tables with the required overall alignment.
  - Program [VTTBR](#) to hold the address of the first of the concatenated translation tables.
  - Program [VTCR](#) to indicate the required input address range and first lookup level.

**Use of concatenated first-level translation tables**

The Long-descriptor format translation tables provide 9 bits of address resolution at each level of lookup. However, a 40-bit input address range with a translation granularity of 4KB requires a total of 28 bits of address resolution. Therefore, a stage 2 translation that supports a 40-bit input address range requires two concatenated first-level translation tables, together aligned to 8KB, where:

- The table at the address with  $PA[12:0] == 0b0\_0000\_0000\_0000$  defines the translations for input addresses with  $bit[39] == 0$ .
- The table at the address with  $PA[12:0] == 0b1\_0000\_0000\_0000$  defines the translations for input addresses with  $bit[39] == 1$ .
- The 8KB alignment requirement means that both table have the same value for  $PA[39:13]$ .

**Use of concatenated second-level translation tables**

A stage 2 translation with an input address range of 31-34 bits can start the translation either:

- With a first-level lookup, accessing a first-level translation table with 2-16 entries.
- With a second-level lookup, accessing a set of concatenated second-level translation tables.

[Table G3-7](#) shows these options, for each of the input address ranges that can use this scheme.

———— **Note** —————

Because these are stage 2 translations, the input address range is an IPA range.

**Table G3-7 Possible uses of concatenated translation tables for second-level lookup**

Input address range		Lookup starts at first level	Lookup starts at second level	
IPA range	Size	Required first-level entries	Number of concatenated tables	Required alignment <sup>a</sup>
IPA[30:0]	2 <sup>31</sup> bytes	2	2	8KB
IPA[31:0]	2 <sup>32</sup> bytes	4	4	16KB
IPA[32:0]	2 <sup>33</sup> bytes	8	8	32KB
IPA[33:0]	2 <sup>34</sup> bytes	16	16	64KB

a. Required alignment of the set of concatenated second-level tables.

See also [Determining the required first lookup level for stage 2 translations on page G3-3605](#).

### G3.6.7 Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format

Figure G3-2 on page G3-3566 shows the possible address translations. The following descriptions of the translations include the registers that control each translation if that translation is controlled from an Exception level that is using AArch32:

#### Stage 1 translations

For all stage 1 translations:

- The input address range is up to 32 bits, as determined by either:
  - **TTBCR.T0SZ** or **TTBCR.T1SZ**, for a PL1&0 stage 1 translation.
  - **HTCR.T0SZ**, for a PL2 stage 1 translation.
- The output address range is 40 bits.

The stage 1 translations are:

#### Non-secure PL1&0 stage 1 translation

The stage 1 translation for memory accesses from Non-secure modes other than Hyp mode. This translates a VA to an IPA. For this translation, when Non-secure EL1 is using AArch32:

- Non-secure **TTBR0** or **TTBR1** holds the translation table base address.
- Non-secure **TTBCR** determines which TTBR is used.

#### Non-secure PL2 stage 1 translation

The stage 1 translation for memory accesses from Hyp mode, translates a VA to a PA. For this translation, when EL2 is using AArch32, **HTTBR** holds the translation table base address.

#### Secure PL1&0 stage 1 translation

The stage 1 translation for memory accesses from Secure modes, translates a VA to a PA. For this translation, when the Secure PL1 modes are using AArch32:

- Secure **TTBR0** or **TTBR1** holds the translation table base address.
- Secure **TTBCR** determines which TTBR is used.

#### Stage 2 translation

##### Non-secure PL1&0 stage 2 translation

The stage 2 translation for memory accesses from Non-secure modes other than Hyp mode, and translates an IPA to a PA. For this translation, when EL2 is using AArch32:

- The input address range is 40 bits, as determined by **VTCR.T0SZ**.
- The output address range depends on the implemented memory system, and is up to 40 bits.
- **VTTBR** holds the translation table base address.
- **VTCR** specifies the required input address range, and whether the first lookup is at the first level or at the second level.

The descriptions of the VMSAv8-32 translation stages state that the maximum output address size is 40 bits. However, the register and Long-descriptor format descriptor fields that hold these addresses are 48 bits wide. If bits[47:40] of an output address are not all zero then the address generates an Address size fault.

The Long-descriptor translation table format provides up to three levels of address lookup, as described in [VMSAv8-32 Long-descriptor translation table format address lookup levels on page G3-3600](#), and the first lookup, in which the MMU reads the translation table base address, is at either the first level or the second level. The following determines the level of the first lookup:

- For a stage 1 translation, the required input address range. For more information see [Determining the required first lookup level for stage 1 translations on page G3-3605](#).

- For a stage 2 translation, the level specified by the **VTCR.SL0** field. For more information see [Determining the required first lookup level for stage 2 translations](#) on page G3-3605.

———— **Note** ————

For a stage 2 translation, the size of the required input address range constrains the **VTCR.SL0** value.

Figure G3-20 shows how the descriptor address for the first lookup for a translation using the Long-descriptor translation table format is determined from the input address and the translation table base register value. This figure shows the lookup for a translation that starts with a first-level lookup, that translates bits[39:30] of the input address, zero extended if necessary.

See text for more information about the translation table base register used, and the value of  $n$ .

‡ This field is absent if  $n$  is 13.

† For a Non-secure PL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

**Figure G3-20 Long-descriptor first lookup, starting at first level**

For a translation that starts with a first-level lookup, as shown in Figure G3-20:

**For a stage 1 translation**

$n$  is in the range 4-5 and:

- For a memory access from Hyp mode:
  - HTTBR** is the translation table base register.
  - $n=5-(HTCR.TOSZ)$ .
- For other accesses:
  - the Secure or Non-secure instance of **TTBR0** or **TTBR1** is the translation table base register.
  - $n=(5-TTBCR.TxSZ)$ , where  $x$  is 0 when using **TTBR0**, and 1 when using **TTBR1**.

**For a stage 2 translation**

$n$  is in the range 4-13 and:

- VTTBR** is the translation table base register.
- $n=5-(VTCT.TOSZ)$ .

For a translation that starts with a second-level lookup, the descriptor address is obtained in the same way, except that bits[( $n+17$ ):21] of the input address provide bits[( $n-1$ ):3] of the descriptor address, where:

**For a stage 1 translation**

$n$  is in the range 7-12. As [Determining the required first lookup level for stage 1 translations](#) on page G3-3605 shows, for a stage 1 translation to start with a second-level lookup, the corresponding **TOSZ** or **TISZ** field must be 2 or more. This means:

- For a memory access from Hyp mode,  $n=14-HTCR.TOSZ$ .

- For other memory accesses,  $n=14-(\text{TTBCR.TxSZ})$ , where  $x$  is 0 when using **TTBR0**, and 1 when using **TTBR1**.

**For a stage 2 translation**

$n$  is in the range 7-16. For a stage 2 translation to start with a second-level lookup, **VTCR.SL0** is 0b00, and  $n=14-(\text{VTCR.TOSZ})$ .

**Determining the required first lookup level for stage 1 translations**

For a stage 1 translation, the required input address range, indicated by a TOSZ or T1SZ field in a translation table control register, determines the first lookup level. The size of this input address region is  $2^{(32-\text{T}x\text{SZ})}$  bytes, and if this size is:

- Less than or equal to  $2^{30}$  bytes, the required start is at the second level, and translation requires two levels of table to map to 4KB pages. This corresponds to a TxSZ value of 2 or more.
- More than  $2^{30}$  bytes, the required start is at the first level, and translation requires three levels of table to map to 4KB pages. This corresponds to a TxSZ value that is less than 2.

For the PL1&0 stage 1 translations, the **TTBCR**:

- Splits the 32-bit VA input address range between **TTBR0** and **TTBR1**, see *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G3-3598*.
- Holds the input address range sizes for **TTBR0** and **TTBR1**, in the **TTBCR.TOSZ** and **TTBCR.T1SZ** fields.

For the PL2 stage 1 translations, **HTCR.TOSZ** indicates the size of the required input address range. For example, if this field is 0b000, it indicates a 32-bit VA input address range, and translation lookup must start at the first level.

**Determining the required first lookup level for stage 2 translations**

For a PL1&0 stage 2 translation, the output address range from the PL1&0 stage 1 translations determines the required input address range for the stage 2 translation.

**VTCR.SL0** indicates the starting level for the lookup. The permitted SL0 values are:

- 0b00 Stage 2 translation lookup must start at the second level.
- 0b01 Stage 2 translation lookup must start at the first level.

In addition, **VTCR.TOSZ** must indicate the required input address range. The size of the input address region is  $2^{(32-\text{TOSZ})}$  bytes.

———— **Note** —————

**VTCR.TOSZ** holds a four-bit signed integer value, meaning it supports values from -8 to 7. This is different from the other translation control registers, where **TnSZ** holds a three-bit unsigned integer, supporting values from 0 to 7.

The programming of **VTCR** must follow the constraints shown in [Table G3-8](#), otherwise behavior is UNPREDICTABLE. The table also shows how the **VTCR.SL0** and **VTCR.TOSZ** values determine the **VTTBR.BADDR** field width.

**Table G3-8 Input address range constraints on programming VTCR**

<b>VTCR.SL0</b>	<b>VTCR.TOSZ</b>	<b>Input address range, R</b>	<b>First lookup level</b>	<b>BADDR[39:x] width<sup>a</sup></b>
0b00	2 to 7	$R \leq 2^{30}$ bytes	Second	[39:12] to [39:7]
0b00	-2 to 1	$2^{30} < R \leq 2^{34}$ bytes	Second	[39:16] to [39:13]
0b01	-2 to 1		First	[39:7] to [39:4]
0b01	-8 to -3	$2^{34} < R$	First	[39:13] to [39:8]

- a. The first range corresponds to the first TOSZ value, the second range to the second TOSZ value.

Where necessary, the first lookup level provides multiple concatenated translation tables, as described in [Use of concatenated second-level translation tables on page G3-3602](#). This section also gives more information about the alternatives, shown in [Table G3-8 on page G3-3605](#), when R is in the range  $2^{31}$ - $2^{34}$ .

### Full translation flows for VMSAv8-32 Long-descriptor format translation tables

In a translation table walk, only the first lookup uses the translation table base address from the appropriate Translation table base register. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

The following sections describe full Long-descriptor format translation flows, down to an entry for a 4KB page:

- [The address and Properties fields shown in the translation flows on page G3-3586](#).
- [Full translation flow, starting at first-level lookup](#).
- [Full translation flow, starting at second-level lookup on page G3-3608](#).

#### **The address and Properties fields shown in the translation flows**

For the Non-secure PL1&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

*Properties* indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see [Information returned by a translation table lookup on page G3-3574](#), and the description of the register or translation table descriptor.

For translations using the Long-descriptor translation table format, [VMSAv8-32 Long-descriptor translation table format descriptors on page G3-3592](#) describes the descriptors formats.

#### **Full translation flow, starting at first-level lookup**

[Figure G3-21 on page G3-3607](#) shows the complete translation flow for a VMSAv8-32 Long-descriptor stage 1 translation table walk that starts with a first-level lookup. For more information about the fields shown in the figure see [The address and Properties fields shown in the translation flows on page G3-3586](#).

For details of *Properties* fields, see the register or descriptor description.

**Figure G3-21 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at first level**

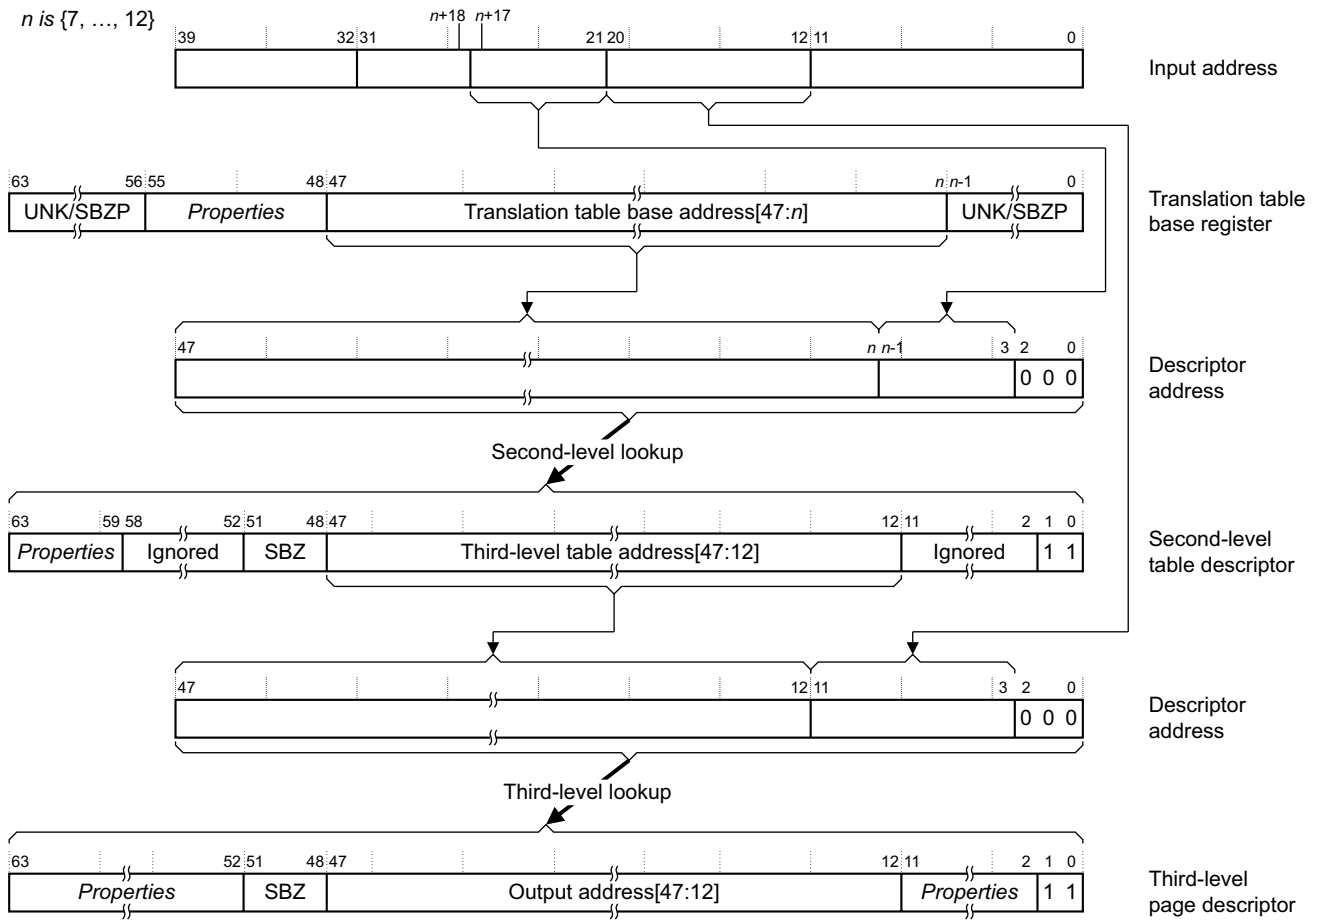

If the first-level lookup or the second-level lookup returns a block descriptor then the translation table walk completes at that level.

A stage 2 translation that starts at a first-level lookup differs from the translation shown in Figure G3-21 only as follows:

- The possible values of  $n$  are 4-13, to support an input address of between 31 and 40 bits.
- A descriptor and output addresses are always PAs.

**Full translation flow, starting at second-level lookup**

Figure G3-22 shows the complete translation flow for a stage 1 VMSAv8-32 Long-descriptor translation table walk that starts at a second-level lookup. For more information about the fields shown in the figure see *The address and Properties fields shown in the translation flows* on page G3-3586.

For details of *Properties* fields, see the register or descriptor description.

**Figure G3-22 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at second level**

If the second-level lookup returns a block descriptor then the translation table walk completes at that level.

A stage 2 translation that starts at a second-level lookup differs from the translation shown in Figure G3-22 only as follows:

- The possible values of  $n$  are 7-16, to support an input address of up to 34 bits.
- The descriptor and output addresses are always PAs.

## G3.7 Memory access control

In addition to an output address, a translation table entry that refers to page or region of memory includes fields that define properties of the target memory region. *Information returned by a translation table lookup on page G3-3574* describes the classification of those fields as address map control, access control, and memory attribute fields. The access control fields, described in this section, determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the translation table descriptor. If a translation stage does not permit the access then a MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:

- [Access permissions.](#)
- [Execute-never restrictions on instruction fetching on page G3-3612.](#)
- [Domains, Short-descriptor format only on page G3-3614.](#)
- [The Access flag on page G3-3615.](#)
- [Hyp mode control of Non-secure access permissions on page G3-3616.](#)

### G3.7.1 Access permissions

#### ———— Note ————

This section gives a general description of memory access permissions. Software executing at PL1 in Non-secure state can see only the access permissions defined by the Non-secure PL1&0 stage 1 translations. However, software executing at PL2 can modify these permissions, as described in [Hyp mode control of Non-secure access permissions on page G3-3616](#). This modification is invisible to Non-secure software executing at EL1 or EL0.

Access permission bits in a translation table descriptor control access to the corresponding memory region. The details of this control depend on the translation table format, as follows:

#### Short-descriptor format

This format supports two options for defining the access permissions:

- Three bits, AP[2:0], define the access permissions.
- Two bits, AP[2:1], define the access permissions, and AP[0] can be used as an Access flag.

[SCTLR.AFE](#) selects the access permissions option. Setting this bit to 1, to enable the Access flag, also selects use of AP[2:1] to define access permissions.

ARM deprecates any use of the AP[2:0] scheme for defining access permissions.

#### Long-descriptor format

AP[2:1] to control the access permissions, and the descriptors provide an AF bit for use as an Access flag. This means VMSAv8-32 behaves as if the value of [SCTLR.AFE](#) is 1, regardless of the value that software has written to this bit.

#### ———— Note ————

When use of the Long-descriptor format is enabled, [SCTLR.AFE](#) is UNK/SBOP.

[The Access flag on page G3-3615](#) describes the Access flag, for both translation table formats.

The XN and PXN bits provide additional access controls for instruction fetches, see [Execute-never restrictions on instruction fetching on page G3-3612](#).

An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation. However, when using the Short-descriptor translation table format, it generates the fault only if the access is to memory in the Client domain, see [Domains, Short-descriptor format only on page G3-3614](#).

———— **Note** —————

For the Non-secure PL1&0 translation regime, memory accesses are subject to two stages of translation. Each stage of translation has its own, independent, fault checking. Fault handling is different for the two stages, see [Exception reporting in a VMSAv8-32 implementation on page G3-3659](#).

The following sections describe the two access permissions models:

- [AP\[2:1\] access permissions model](#).
- [AP\[2:0\] access permissions control, Short-descriptor format only on page G3-3611](#). This section includes some information on access permission control in earlier versions of the ARM VMSA.

### AP[2:1] access permissions model

———— **Note** —————

ARM recommends that this model is always used, even where the AP[2:0] model is permitted. Some documentation describes the AP[2:1] model as the *simplified access permissions* model.

This access permissions model is used if the translation is either:

- Using the Long-descriptor translation table format.
- Using Short-descriptor translation table format, and the [SCTLR.AFE](#) bit is set to 1.

In this model:

- One bit, AP[2], selects between read-only and read/write access.
- A second bit, AP[1], selects between Application level (PL0) and System level (PL1) control. For the Non-secure PL2 stage 1 translations, AP[1] is SBO.

This provides four access combinations:

- Read-only at all privilege levels.
- Read/write at all privilege levels.
- Read-only at PL1, no access by software executing at PL0.
- Read/write at PL1, no access by software executing at PL0.

[Table G3-9](#) shows this access control model.

**Table G3-9 VMSAv8-32 AP[2:1] access permissions model**

AP[2], disable write access	AP[1], enable unprivileged access	Access
0	0 <sup>a</sup>	Read/write, only at PL1
0	1	Read/write, at any privilege level
1	0 <sup>a</sup>	Read-only, only at PL1
1	1	Read-only, at any privilege level

a. Not valid for Non-secure PL2 stage 1 translation tables. AP[1] is SBO in these tables.

#### **Hierarchical control of access permissions, Long-descriptor format**

The Long-descriptor translation table format introduces a mechanism that entries at one level of translation table lookup can use to set limits on the permitted entries at subsequent levels of lookup. This applies to the access permissions, and also to the restrictions on instruction fetching described in [Hierarchical control of instruction fetching, Long-descriptor format on page G3-3613](#).

The restrictions apply only to subsequent levels of lookup at the same stage of translation. The APTable[1:0] field restricts the access permissions, as [Table G3-10 on page G3-3611](#) shows.

As stated in the table footnote, for the Non-secure PL2 stage 1 translation tables, APTable[0] is reserved, SBZ.

**Table G3-10 Effect of APTable[1:0] on subsequent levels of lookup**

APTable[1:0]	Effect
00	No effect on permissions in subsequent levels of lookup.
01 <sup>a</sup>	Access at PL0 not permitted, regardless of permissions in subsequent levels of lookup.
10	Write access not permitted, at any exception level, regardless of permissions in subsequent levels of lookup.
11 <sup>a</sup>	Regardless of permissions in subsequent levels of lookup: <ul style="list-style-type: none"> <li>• Write access not permitted, at any exception level.</li> <li>• Read access not permitted at PL0.</li> </ul>

a. Not valid for the Non-secure PL2 stage 1 translation tables. In those tables, APTable[0] is SBZ.

**Note**

The APTable[1:0] settings are combined with the translation table access permissions in the translation tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The Long-descriptor format provides APTable[1:0] control only for the stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

When APTable[1:0] is not set to 0b00, its effects might be held in one or more TLB entries. Therefore, a change to APTable[1:0] might require coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

**AP[2:0] access permissions control, Short-descriptor format only**

This access permissions model applies when using the Short-descriptor translation tables format, and the SCTLR.AFE bit is set to 0. ARM deprecates any use of this access permissions model.

When SCTLR.AFE is set to 0, ensuring that the AP[0] bit is always set to 1 effectively changes the access model to the simpler model described in *AP[2:1] access permissions model on page G3-3610*.

Table G3-11 shows the full AP[2:0] access permissions model:

**Table G3-11 VMSAv8-32 MMU access permissions**

AP[2]	AP[1:0]	EL1 and EL2 access	Unprivileged access	Description
0	00	No access	No access	All accesses generate Permission faults
	01	Read/write	No access	Access only at PL1 or higher
	10	Read/write	Read-only	Writes at PL0 generate Permission faults
	11	Read/write	Read/write	Full access
1	00	-	-	Reserved
	01	Read-only	No access	Read-only, only at PL1 or higher
	10	Read-only	Read-only	Read-only at any exception level, deprecated <sup>a</sup>
	11	Read-only	Read-only	Read-only at any exception level <sup>b</sup>

a. From VMSAv7, ARM strongly recommends use of the 0b11 encoding for Read-only at any exception level.

b. This mapping was introduced in VMSAv7, and is reserved in earlier versions of the VMSA.

———— **Note** ————

- VMSAv8-32 supports the full set of access permissions shown in [Table G3-11 on page G3-3611](#) only when `SCTLR.AFE` is set to 0. When `SCTLR.AFE` is set to 1, the only supported access permissions are those described in [AP\[2:1\] access permissions model on page G3-3610](#).
- Some old documentation describes the AP[2] bit in the translation table entries as the APX bit.

### G3.7.2 Execute-never restrictions on instruction fetching

Execute-never (XN) controls provide an additional level of control on memory accesses permitted by the access permissions settings. These controls are:

#### XN, Execute-never

When the XN bit is 1, a Permission fault is generated if the PE attempts to execute an instruction fetched from the corresponding memory region. However, when using the Short-descriptor translation table format, the fault is generated only if the access is to memory in the Client domain, see [Domains, Short-descriptor format only on page G3-3614](#). A PE can execute instructions from a memory region only if the access permissions for its current state permit read access, and the XN bit is set to 0.

#### PXN, Privileged execute-never

When the PXN bit is 1, a Permission fault is generated if the PE is executing at PL1 and attempts to execute an instruction fetched from the corresponding memory region. As with the XN bit, when using the Short-descriptor translation table format, the fault is generated only if the access is to memory in the Client domain.

In both the Short-descriptor format and the Long-descriptor format translation tables, all descriptors for memory blocks and pages always include an XN bit.

Support for the PXN bit is as follows:

- The Long-descriptor translation table formats always include the PXN bit.
- All implementations must:
  - Support the use of the PXN bit.
  - Use the Short-descriptor translation table formats that include the PXN bit.

In the Non-secure PL2 stage 1 translation tables, the PXN bit is reserved, SBZ.

In addition, additional controls can enforce execute-never restrictions, regardless of the settings in the translation tables, see:

- [Restriction on Secure instruction fetch on page G3-3613](#).
- [Preventing execution from writable locations on page G3-3614](#).

The execute-never controls apply also to speculative instruction fetching. This means a speculative instruction fetch from a memory region that is execute-never at the current level of privilege is prohibited.

The XN control means that, when the stage of address translation is enabled, the PE can fetch, or speculatively fetch, an instruction from a memory location only if all of the following apply:

- If using the Short-descriptor translation table format, the translation table descriptor for the location does not indicate that it is in a No access domain.
- If using the Long-descriptor translation table format, or using the Short descriptor format and the descriptor indicates that the location is in a Client domain, in the descriptor for the location the following apply:
  - XN is set to 0.
  - The access permissions permit a read access from the current PE mode.
- No other Prefetch Abort condition exists.

---

**Note**

- The PXN control applies to the PE privilege when it attempts to execute the instruction. In an implementation that fetches instructions speculatively, this might not be the privilege when the instruction was prefetched. Therefore, the architecture does not require the PXN control to prevent instruction fetching.
- Although the XN control applies to speculative fetching, on a speculative instruction fetch from an XN location, no Permission fault is generated unless the PE attempts to execute the instruction fetched from that location. This means that, if a speculative fetch from an XN location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated.
- The software that defines a translation table must mark any region of memory that is read-sensitive as XN, to avoid the possibility of a speculative fetch accessing the memory region. For example, it must mark any memory region that corresponds to a read-sensitive peripheral as XN.
- When using the Short-descriptor translation table format, the XN attribute is not checked for domains marked as Manager. Therefore, the system must not include read-sensitive memory in domains marked as Manager, because the XN bit does not prevent speculative fetches from a Manager domain.

---

When no stage of address translation for the translation regime is enabled, memory regions cannot have XN or PXN attributes assigned. [Behavior of instruction fetches when all associated address translations are disabled on page G3-3571](#) describes how disabling all MMUs affects instruction fetching.

### Hierarchical control of instruction fetching, Long-descriptor format

The Long-descriptor translation table format introduces a mechanism that means entries at one level of translation tables lookup can set limits on the permitted entries at subsequent levels of lookup. This applies to the restrictions on instruction fetching, and also to the access permissions described in [Hierarchical control of access permissions, Long-descriptor format on page G3-3610](#).

The restrictions apply only to subsequent levels of lookup at the same stage of translation, and:

- XNTable restricts the XN control:
  - When XNTable is set to 1, the XN bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
  - When XNTable is set to 0 it has no effect.
- PXNTable restricts the PXN control:
  - When PXNTable is set to 1, the PXN bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
  - When PXNTable is set to 0 it has no effect.

---

**Note**

The XNTable and PXNTable settings are combined with the XN and PXN bits in the translation table descriptors accessed at subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The XNTable and PXNTable controls are provided only in the Long-descriptor translation table format, and only for stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

When XNTable, or PXNTable, is set to 1, its effects might be held in one or more TLB entries. Therefore, a change to XNTable or PXNTable might require coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

### Restriction on Secure instruction fetch

EL3 provides a Secure instruction fetch bit, [SCR.SIF](#). When this bit is set to 1, any attempt in Secure state to execute an instruction fetched from Non-secure physical memory causes a Permission fault. As with all Permission fault checking, when using the Short-descriptor format translation tables the check applies only to Client domains, see [Access permissions on page G3-3609](#).

ARM expects `SCR.SIF` to be static during normal operation. In particular, whether the TLB holds the effect of the SIF bit is IMPLEMENTATION DEFINED. The generic sequence to ensure visibility of a change to the SIF bit is:

```
Change the SCR.SIF bit
ISB                ; This ensures synchronization of the change
Invalidate entire TLB
DSB                ; This completes the TLB Invalidation
ISB                ; This ensures instruction synchronization
```

### Preventing execution from writable locations

The architecture includes control bits that, when the corresponding stage 1 address translation is enabled, force writable memory to be treated as XN, regardless of the setting of the XN bit. When the translation stages are controlled by an Exception level that is using AArch32:

- For PL1&0 stage 1 translations, when `SCTLR.WXN` is set to 1, all regions that are writable at stage 1 of the address translation are treated as XN.
- For Non-secure PL2 stage 1 translations, when `HSCTLR.WXN` is set to 1, all regions that are writable at stage 1 of the address translation are treated as XN.
- For PL1&0 stage 1 translations, when `SCTLR.UWXN` is set to 1, an instruction fetch is treated as accessing a PXN region if it accesses a region that software executing at PL0 can write to.

#### Note

Setting a WXN or UWXN bit to 1 changes the interpretation of the translation table entry, overriding a zero value of an XN or PXN field. It does not cause any change to the translation table entry.

For any given virtual machine, ARM expects WXN and UWXN to remain static in normal operation. In particular, it is IMPLEMENTATION DEFINED whether TLB entries associated with a particular VMID reflect the effect of the values of these bits. A generic sequence to ensure synchronization of a change to these bits, when that change is made without a corresponding change of VMID, is:

```
Change the WXN or UWXN bit
ISB                ; This ensures synchronization of the change
Invalidate entire TLB of associated entries
DSB                ; This completes the TLB Invalidation
ISB                ; This ensures instruction synchronization
```

As with all Permission fault checking, if the stage 1 translation is using the Short-descriptor translation table format, the permission checks are performed only for Client domains. For more information see [Access permissions on page G3-3609](#).

For more information about address translation see [About address translation for VMSEA8-32 on page G3-3565](#).

### G3.7.3 Domains, Short-descriptor format only

A domain is a collection of memory regions. The Short-descriptor translation table format supports 16 domains, and requires the software that defines a translation table to assign each VMSEA8-32 memory region to a domain. When using the Short-descriptor format:

- First-level translation table entries for Page tables and Sections include a domain field.
- Translation table entries for Supersections do not include a domain field. The Short-descriptor format defines Supersections as being in domain 0.
- Second-level translation table entries inherit a domain setting from the parent first-level Page table entry.
- Each TLB entry includes a domain field.

The domain field specifies which of the 16 domains the entry is in, and a two-bit field in the [DACR](#) defines the permitted access for each domain. The possible settings for each domain are:

- No access** Any access using the translation table descriptor generates a Domain fault.
- Clients** On an access using the translation table descriptor, the access permission attributes are checked. Therefore, the access might generate a Permission fault.
- Managers** On an access using the translation table descriptor, the access permission attributes are not checked. Therefore, the access cannot generate a Permission fault.

See [The MMU fault-checking sequence on page G3-3650](#) for more information about how, when using the Short-descriptor translation table format, the Domain attribute affects the checking of the other attributes in the translation table descriptor.

———— **Note** —————

A single program might:

- Be a Client of some domains.
- Be a Manager of some other domains.
- Have no access to the remaining domains.

The Long-descriptor translation table format does not support domains. When a stage of translation is using this format, all memory is treated as being in a Client domain, and the settings in the [DACR](#) are ignored.

### G3.7.4 The Access flag

The Access flag indicates when a page or section of memory is accessed for the first time since the Access flag in the corresponding translation table descriptor was set to 0:

- If address translation is using the Short-descriptor translation table format, it must set [SCTLR.AFE](#) to 1 to enable use of the Access flag, see [SCTLR, System Control Register on page G4-4005](#). Setting this bit to 1 redefines the AP[0] bit in the translation table descriptors as an Access flag, and limits the access permissions information in the translation table descriptors to AP[2:1], as described in [AP\[2:1\] access permissions model on page G3-3610](#).
- The Long-descriptor format always supports an Access flag bit in the translation table descriptors, and address translation using this format behaves as if [SCTLR.AFE](#) is set to 1, regardless of the value of that bit.

In ARMv8 the Access flag is managed by software as described in the following subsection.

———— **Note** —————

Previous version of the ARM architecture optionally supported hardware management of the Access flag. ARMv8 obsoletes this option.

#### Software management of the Access flag

An implementation that requires software to manage the Access flag generates an Access flag fault whenever a translation table entry with the Access flag set to 0 is read into the TLB

———— **Note** —————

When using the Short-descriptor translation table format, Access flag faults are generated only if [SCTLR.AFE](#) is set to 1, to enable use of a translation table descriptor bit as an Access flag.

The Access flag mechanism expects that, when an Access flag fault occurs, software resets the Access flag to 1 in the translation table entry that caused the fault. This prevents the fault occurring the next time that memory location is accessed. Entries with the Access flag set to 0 are never held in the TLB, meaning software does not have to flush the entry from the TLB after setting the flag.

### G3.7.5 Hyp mode control of Non-secure access permissions

When EL2 is using AArch32, Non-secure software executing in Hyp mode controls two sets of translation tables, both of which use the Long-descriptor translation table format:

- The translation tables that control the Non-secure PL2 stage 1 translations. These map VAs to PAs, for memory accesses made when executing in Non-secure state in Hyp mode, and are indicated and controlled by the [HTTBR](#) and [HTCR](#).

These translations have similar access controls to other Non-secure stage 1 translations using the Long-descriptor translation table format, as described in:

- [AP\[2:1\] access permissions model on page G3-3610](#).
- [Execute-never restrictions on instruction fetching on page G3-3612](#).

The differences from the Non-secure stage 1 translations are that:

- The APTable[0], PXNTable, and PXN bits are reserved, SBZ.
- AP[1] is reserved, SBO.

- The translation tables that control the Non-secure PL1&0 stage 2 translations. These map the IPAs from the stage 1 translation onto PAs, for memory accesses made when executing in Non-secure state at PL1 or PL0, and are indicated and controlled by the [VTTBR](#) and [VTCR](#).

The descriptors in the virtualization translation tables define a second level of access permissions, that are combined with the permissions defined in the stage 1 translation. This section describes this combining of access permissions.

———— **Note** —————

The second-level access permissions mean a hypervisor can define additional access restrictions to those defined by a Guest OS in the stage 1 translation tables. For a particular access, the actual access permission is the more restrictive of the permissions defined by:

- The Guest OS, in the stage 1 translation tables.
- The hypervisor, in the stage 2 translation tables.

The stage 2 access controls defined from Hyp mode:

- Affect only the Non-secure stage 1 access permissions settings.
- Take no account of whether the accesses are from a Non-secure PL1 mode or a Non-secure PL0 mode.
- Permit software executing in Hyp mode to assign a write-only attribute to a memory region.

The S2AP field in the stage 2 descriptors define the stage 2 access permissions, as [Table G3-12](#) shows:

**Table G3-12 Stage 2 control of access permissions**

S2AP	Access permission
00	No access permitted
01	Read-only. Writes to the region are not permitted, regardless of the stage 1 permissions.
10	Write-only. Reads from the region are not permitted, regardless of the stage 1 permissions.
11	Read/write. The stage 1 permissions determine the access permissions for the region.

For more information about the S2AP field see [Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors on page G3-3596](#).

If the stage 2 permissions cause a Permission fault, this is a stage 2 address translation fault. Stage 2 address translation faults are taken to Hyp mode, and reported in the [HSR](#) using an EC code of 0x20 or 0x24. For more information, see [Use of the HSR on page G3-3672](#).

---

**Note**

---

The combination of the EC code and the STATUS value in the [HSR](#) indicate that the fault is a stage 2 address translation fault.

---

The stage 2 permissions include an XN attribute. If this is set to 1, execution from the region is not permitted, regardless of the value of the XN attribute in the stage 1 translation. If a Permission fault is generated because the stage 2 XN bit is set to 1, this is reported as a stage 2 address translation fault.

*[Prioritization of aborts on page G3-3658](#) describes the abort prioritization if both stages of a translation generate a fault.*

## G3.8 Memory region attributes

In addition to an output address, a translation table entry that refers to a page or region of memory includes fields that define properties of that target memory region. [Information returned by a translation table lookup on page G3-3574](#) describes the classification of those fields as address map control, access control, and memory attribute fields. The memory region attribute fields control the memory type, accesses to the caches, and whether the memory region is Shareable and therefore is coherent.

The following sections describe the assignment of memory region attributes for stage 1 translations:

- [Overview of memory region attributes for stage 1 translations.](#)
- [Short-descriptor format memory region attributes, without TEX remap on page G3-3619.](#)
- [Short-descriptor format memory region attributes, with TEX remap on page G3-3620.](#)
- [VMSAv8-32 Long-descriptor format memory region attributes on page G3-3624.](#)

For an implementation that is operating in Secure state, or in Hyp mode, these assignments define the memory attributes of the accessed region.

For an implementation that is operating in a Non-secure PL1 or PL0 mode, the Non-secure PL1&0 stage 2 translation can modify the memory attributes assigned by the stage 1 translation. [EL2 control of Non-secure memory region attributes on page G3-3625](#) describes these stage 2 assignments.

### G3.8.1 Overview of memory region attributes for stage 1 translations

The description of the memory region attributes in a translation descriptor divides into:

#### Memory type and attributes

These are described either:

- Directly, by bits in the translation table descriptor.
- Indirectly, by registers referenced by bits in the table descriptor. This is described as *remapping* the memory type and attribute description.

The Short-descriptor translation table format can use either of these approaches, selected by the `SCTLR.TRE` bit:

**TRE == 0** Remap disabled. The `TEX[2:0]`, `C`, and `B` bits in the translation table descriptor define the memory region attributes. [Short-descriptor format memory region attributes, without TEX remap on page G3-3619](#) describes this encoding.

———— **Note** —————

With the Short-descriptor format, remapping is called *TEX remap*, and the `SCTLR.TRE` bit is the *TEX remap enabled* bit.

The description of the `TRE == 0` encoding includes information about the encoding in previous versions of the architecture.

**TRE == 1** Remap enabled. The `TEX[0]`, `C`, and `B` bits in the translation table descriptor are index bits to the remap registers, that define the memory region attributes:

- The Primary Region Remap Register, `PRRR`.
- The Normal Memory Remap Register, `NMRR`.

[Short-descriptor format memory region attributes, with TEX remap on page G3-3620](#) describes this encoding scheme.

This scheme reassigns translation table descriptor bits `TEX[2:1]` for use as bits managed by the operating system.

The Long-descriptor translation table format always uses remapping. This means VMSAv8-32 behaves as if the value of `SCTLR.TRE` is 1, regardless of the value that software has written to this bit.

———— **Note** —————

When use of the Long-descriptor format is enabled, `SCTLR.TRE` is `UNK/SBOP`.

[VMSAv8-32 Long-descriptor format memory region attributes on page G3-3624](#) describes this encoding.

**Shareability** In the Short-descriptor translation table format, the S bit in the translation table descriptor encodes whether the region is shareable. Enabling TEX remap extends the shareability description. For more information see:

- [Shareability and the S bit, without TEX remap on page G3-3620](#).
- [Shareability and the S bit, with TEX remap on page G3-3622](#).

In the Long-descriptor translation table format, the SH[1:0] field in the translation table descriptor encodes shareability information. For more information see [Shareability, Long-descriptor format on page G3-3624](#).

### G3.8.2 Short-descriptor format memory region attributes, without TEX remap

When using the Short-descriptor translation table formats, TEX remap is disabled when `SCTLR.TRE` is set to 0.

———— **Note** —————

- The Short-descriptor format scheme without TEX remap is the scheme used in VMSAv6.
- The B (Bufferable), C (Cacheable), and TEX (Type extension) bit names are inherited from earlier versions of the architecture. These names no longer adequately describe the function of the B, C, and TEX bits.

[Table G3-13](#) shows the C, B, and TEX[2:0] encodings when TEX remap is disabled:

**Table G3-13 TEX, C, and B encodings when TRE == 0**

TEX[2:0]	C	B	Description	Memory type	Page Shareable
000	0	0	Device-nGnRnE	Device-nGnRnE	Shareable
		1	Shareable Device-nGnRE <sup>a</sup>	Device-nGnRE	Shareable <sup>a</sup>
	1	0	Outer and Inner Write-Through, no Write-Allocate	Normal	S bit <sup>b</sup>
		1	Outer and Inner Write-Back, no Write-Allocate	Normal	S bit <sup>b</sup>
001	0	0	Outer and Inner Non-cacheable	Normal	S bit <sup>b</sup>
		1	Reserved	-	-
	1	0	IMPLEMENTATION DEFINED	IMPLEMENTATION DEFINED	IMPLEMENTATION DEFINED
		1	Outer and Inner Write-Back, Write-Allocate	Normal	S bit <sup>b</sup>
010	0	0	Non-shareable Device-nGnRE <sup>a</sup>	Device-nGnRE	Non-shareable <sup>a</sup>
		1	Reserved	-	-
	1	x	Reserved	-	-
011	x	x	Reserved	-	-
1BB	A	A	Cacheable memory: AA = Inner attribute <sup>c</sup> BB = Outer attribute	Normal	S bit <sup>b</sup>

- Some implementations make no distinction between Shareable Device-nGnRE memory and Non-shareable Device-nGnRE memory, and refer to both memory types as Shareable Device-nGnRE memory.
- For more information, see [Shareability and the S bit, without TEX remap on page G3-3620](#).
- For more information, see [Cacheable memory attributes, without TEX remap on page G3-3620](#).

See [Memory types and attributes on page E2-2357](#) for an explanation of Normal memory, and the types of Device memory, and of the shareability attribute.

### Cacheable memory attributes, without TEX remap

When  $TEX[2] == 1$ , the memory described by the translation table entry is Cacheable, and the rest of the encoding defines the Inner and Outer cache attributes:

- TEX[1:0]** Define the Outer cache attribute.
- C, B** Define the Inner cache attribute.

The translation table entries use the same encoding for the Outer and Inner cache attributes, as [Table G3-14](#) shows.

**Table G3-14 Inner and Outer cache attribute encoding**

Encoding	Cache attribute
00	Non-cacheable
01	Write-Back, Write-Allocate
10	Write-Through, no Write-Allocate
11	Write-Back, no Write-Allocate

### Shareability and the S bit, without TEX remap

The translation table entries also include an S bit. This bit:

- Is ignored if the entry refers to any type of Device memory.
- For Normal memory, determines whether the memory region is Shareable or Non-shareable:
  - S == 0** Normal memory region is Non-shareable.
  - S == 1** Normal memory region is Shareable.

## G3.8.3 Short-descriptor format memory region attributes, with TEX remap

When using the Short-descriptor translation table formats, TEX remap is enabled when **SCTLR.TRE** is set to 1. In this configuration:

- The software that defines the translation tables must program the **PRRR** and **NMRR** to define seven possible memory region attributes.
- The **TEX[0]**, **C**, and **B** bits of the translation table descriptors define the memory region attributes, by indexing **PRRR** and **NMRR**.
- Hardware makes no use **TEX[2:1]**, see [The OS managed translation table bits on page G3-3623](#).

When TEX remap is enabled:

- For seven of the eight possible combinations of the **TEX[0]**, **C** and **B** bits, fields in the **PRRR** and **NMRR** define the region attributes, as described in this section.
- The meaning of the eighth combination for the **TEX[0]**, **C** and **B** bits is IMPLEMENTATION DEFINED.
- Four bits in the **PRRR** define whether the region is shareable, as described in [Shareability and the S bit, with TEX remap on page G3-3622](#).

For each of the possible encodings of the TEX[0], C, and B bits in a translation table entry, [Table G3-15](#) shows which fields of the [PRRR](#) and [NMRR](#) registers describe the memory region attributes.

**Table G3-15 TEX, C, and B encodings when TRE == 1**

Encoding TEX[0]	C	B	Memory type <sup>a</sup>	Cache attributes <sup>a, b</sup> :		Outer Shareable attribute <sup>a, c</sup>
				Inner cacheability	Outer cacheability	
0	0	0	<a href="#">PRRR</a> [1:0]	<a href="#">NMRR</a> [1:0]	<a href="#">NMRR</a> [17:16]	NOT( <a href="#">PRRR</a> [24])
		1	<a href="#">PRRR</a> [3:2]	<a href="#">NMRR</a> [3:2]	<a href="#">NMRR</a> [19:18]	NOT( <a href="#">PRRR</a> [25])
	1	0	<a href="#">PRRR</a> [5:4]	<a href="#">NMRR</a> [5:4]	<a href="#">NMRR</a> [21:20]	NOT( <a href="#">PRRR</a> [26])
		1	<a href="#">PRRR</a> [7:6]	<a href="#">NMRR</a> [7:6]	<a href="#">NMRR</a> [23:22]	NOT( <a href="#">PRRR</a> [27])
1	0	0	<a href="#">PRRR</a> [9:8]	<a href="#">NMRR</a> [9:8]	<a href="#">NMRR</a> [25:24]	NOT( <a href="#">PRRR</a> [28])
		1	<a href="#">PRRR</a> [11:10]	<a href="#">NMRR</a> [11:10]	<a href="#">NMRR</a> [27:26]	NOT( <a href="#">PRRR</a> [29])
	1	0	IMPLEMENTATION DEFINED			
		1	<a href="#">PRRR</a> [15:14]	<a href="#">NMRR</a> [15:14]	<a href="#">NMRR</a> [31:30]	NOT( <a href="#">PRRR</a> [31])

- For details of the *Memory type* and *Outer Shareable* encodings see [PRRR, Primary Region Remap Register](#) on page G4-3992. For details of the *Cache attributes* encodings see [Table G3-14](#) on page G3-3620.
- Applies only if the memory type for the region is mapped as Normal memory.
- Applies only if the memory type for the region is mapped as Normal or Device-nGnRE memory and the region is Shareable.

The TEX remap registers and the [SCTLR.TRE](#) bit are Banked between the Secure and Non-secure Security states. For more information, see [The effect of EL3 on TEX remap](#) on page G3-3624.

When TEX remap is enabled, the mappings specified by the [PRRR](#) and [NMRR](#) determine the mapping of the TEX[0], C and B bits in the translation tables to memory type and cacheability attributes:

- The primary mapping, indicated by a field in the [PRRR](#) as shown in the *Memory type* column of [Table G3-15](#), takes precedence.
- For any region that the [PRRR](#) maps as Normal memory, the [NMRR](#) determines the Inner cacheability and Outer cacheability attributes.
- If it is supported, the Outer Shareable mapping identifies Shareable memory as either Inner Shareable or Outer Shareable, see [Interpretation of the NOSn fields in the PRRR, with TEX remap](#) on page G3-3622.

The TEX remap registers must be static during normal operation. In particular, when the remap registers are changed:

- It is IMPLEMENTATION DEFINED when the changes take effect.
- It is UNPREDICTABLE whether the TLB caches the effect of the TEX remap on translation tables.

The software sequence to ensure the synchronization of changes to the TEX remap registers is:

- Execute a DSB instruction. This ensures any memory accesses using the old mapping have completed.
- Write the TEX remap registers or [SCTLR.TRE](#) bit.
- Execute an ISB instruction. This ensures synchronization of the register updates.
- Invalidate the entire TLB.
- Execute a DSB instruction. This ensures completion of the entire TLB operation.
- Clean and invalidate all caches. This removes any cached information associated with the old mapping.
- Execute a DSB instruction. This ensures completion of the cache maintenance.
- Execute an ISB instruction. This ensures instruction synchronization.

This extends the standard rules for the synchronization of changes to System registers described in *Synchronization of changes to System registers* on page G3-3706, and provides implementation freedom as to whether or not the effect of the TEX remap is cached.

### Shareability and the S bit, with TEX remap

The memory type of a region, as indicated in the *Memory type* column of Table G3-15 on page G3-3621, provides the first level of control of whether the region is shareable:

- If using the Long-descriptor translation table format, if the memory is any type of Device memory then the region is Shareable.
- If using the Short descriptor translation table format then:
  - If the memory is Device-nGnRnE memory then the region is Shareable.
  - Otherwise, the shareability is determined by using the value of the S bit in the translation table descriptor to index bits in the *PRRR*.

Some implementations make no distinction between Shareable Device-nGnRE memory and Non-shareable Device-nGnRE memory, and refer to both memory types as Shareable Device memory.
- If the memory type is Normal then the shareability is determined by using the value of the S bit in the translation table descriptor to index bits in the *PRRR*.

Table G3-16 shows this determination:

**Table G3-16 Determining shareability, with TEX remap**

Memory type	Remapping when S == 0	Remapping when S == 1
Any type of Device	Shareable	Shareable
Normal	<i>PRRR</i> [18]	<i>PRRR</i> [19]

In the cases where the shareability is remapped, the appropriate bit of the *PRRR* indicates whether the region is Shareable or Non-shareable, as follows:

*PRRR*[n] == 0      Not shareable.

*PRRR*[n] == 1      Shareable.

———— **Note** —————

When TEX remap is enabled, a translation table entry with S == 0 can be mapped as Shareable memory.

### Interpretation of the NOSn fields in the *PRRR*, with TEX remap

When all of the following apply, the NOSn fields in the *PRRR* distinguish between Inner Shareable and Outer Shareable memory regions:

- The *SCTLR.TRE* bit is set to 1.
- The region is mapped as Normal memory, or the Short-descriptor translation table format is used and the region is mapped as Device-nGnRE memory.
- The Normal memory remapping or Device-nGnRE memory remapping of the S bit value for the entry makes the region Shareable.
- The implementation supports the distinction between Inner Shareable and Outer Shareable.

If the *SCTLR.TRE* bit is set to 0, an implementation can provide an IMPLEMENTATION DEFINED mechanism to interpret the NOSn fields in the *PRRR*, see *SCTLR.TRE*, *SCTLR.M*, and the effect of the TEX remap registers on page G3-3623.

The values of the NOSn fields in the [PRRR](#) have no effect.

The NOSn fields in the [PRRR](#) are RAZ/WI if the implementation does not support the distinction between Inner Shareable and Outer Shareable memory regions.

———— **Note** —————

The meaning of shareability attributes for Device-nGnRE memory is IMPLEMENTATION DEFINED when the Short-descriptor translation table is used, and otherwise has no meaning.

## SCTLR.TRE, SCTLR.M, and the effect of the TEX remap registers

When TEX remap is disabled, because the [SCTLR.TRE](#) bit is set to 0:

- The effect of the [PRRR](#) and [NMRR](#) registers can be IMPLEMENTATION DEFINED.
- The interpretation of the fields of the [PRRR](#) and [NMRR](#) registers can differ from the description given earlier in this section.

VMSAv8-32 requires that the effect of these registers is limited to remapping the attributes of memory locations. These registers must not change whether any cache hardware or stages of address translation are enabled. The mechanism by which the TEX remap registers have an effect when the [SCTLR.TRE](#) bit is set to 0 is IMPLEMENTATION DEFINED. The AArch32 architecture requires that from reset, if the IMPLEMENTATION DEFINED mechanism has not been invoked:

- If the EL1&0 stage 1 address translation is enabled and is using the Short-descriptor format translation tables, the architecturally-defined behavior of the TEX[2:0], C, and B bits must apply, without reference to the TEX remap functionality. In other words, memory attribute assignment must comply with the scheme described in *Short-descriptor format memory region attributes, without TEX remap* on page G3-3619.
- If the EL1&0 stage 1 address translation is disabled, then the architecturally-defined behavior of VMSAv8-32 with address translation disabled must apply, without reference to the TEX remap functionality. See *The effects of disabling address translation stages on VMSAv8-32 behavior* on page G3-3569.

Possible mechanisms for enabling the IMPLEMENTATION DEFINED effect of the TEX remap registers when [SCTLR.TRE](#) is set to 0 include:

- A control bit in the [ACTLR](#), or in an IMPLEMENTATION DEFINED System register.
- Changing the behavior when the [PRRR](#) and [NMRR](#) registers are changed from their IMPLEMENTATION DEFINED reset values.

In addition, if the stage of address translation is disabled and the [SCTLR.TRE](#) bit is set to 1, the architecturally-defined behavior of the VMSAv8-32 with the stage of address translation disabled must apply without reference to the TEX remap functionality.

In an implementation that includes EL3, the IMPLEMENTATION DEFINED effect of these registers must only take effect in the Security state of the registers. See also *The effect of EL3 on TEX remap* on page G3-3624.

## The OS managed translation table bits

When TEX remap is enabled, the TEX[2:1] bits in the translation table descriptors are available as two bits that can be managed by the operating system. In VMSAv8-32, as long as the [SCTLR.TRE](#) bit is set to 1, the values of the TEX[2:1] bits are ignored by the memory management hardware. Software can write any value to these bits in the translation tables.

### The effect of EL3 on TEX remap

In an implementation that includes EL3, the TEX remap registers are Banked between the Secure and Non-secure Security states. The register instances for the current security state apply to all PL1&0 stage 1 translation table lookups in that state. The **SCTLR.TRE** bit is Banked in the Secure and Non-secure copies of the register, and the appropriate version of this bit determines whether TEX remap is applied to translation table lookups in the current security state.

Write accesses to the Secure copies of the TEX remap registers are disabled when the **CP15SDISABLE** input is asserted HIGH, meaning the MCR operations to access these registers are UNDEFINED. For more information, see [The CP15SDISABLE input on page G3-3704](#).

### G3.8.4 VMSAv8-32 Long-descriptor format memory region attributes

When a PE is using the VMSAv8-32 Long-descriptor translation table format, the **AttrIdx[2:0]** field in a block or page translation table descriptor for a stage 1 translation indicates the 8-bit field in the appropriate MAIR register, that specifies the attributes for the corresponding memory region, as follows:

- **AttrIdx[2]** indicates the MAIR register to be used:  
**AttrIdx[2] == 0**     Use [MAIR0](#).  
**AttrIdx[2] == 1**     Use [MAIR1](#).
- **AttrIdx[2:0]** indicates the required **Attr** field, **Attr<sub>n</sub>**, where  $n = \text{AttrIdx}[2:0]$ .

Each **AttrIdx** field defines, for the corresponding memory region:

- The memory type, Normal or a type of Device memory.
- For Normal memory:
  - The inner and outer cacheability, Non-cacheable, Write-Through, or Write-Back.
  - For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate policy hints, each of which is *Allocate* or *Do not allocate*.

For more information about the **AttrIdx[2:0]** descriptor field, see [Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors on page G3-3595](#).

### Shareability, Long-descriptor format

When a PE is using the Long-descriptor translation table format, the **SH[1:0]** field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region, if the MAIR entry for that region identifies it as Normal memory. [Table G3-17](#) shows the encoding of this field.

**Table G3-17 SH[1:0] field encoding for Normal memory, Long-descriptor format**

SH[1:0]	Normal memory
00	Non-shareable
01	UNPREDICTABLE
10	Outer Shareable
11	Inner Shareable

See [Combining the shareability attribute on page G3-3629](#) for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

For any type of Device memory, the value of the **SH[1:0]** field of the translation table descriptor is ignored.

## Other fields in the Long-descriptor translation table format descriptors

The following subsections describe the other fields in the translation table block and page descriptors when a PE is using the Long-descriptor translation table format:

- [Contiguous bit](#)
- [Field reserved for software use](#)
- [Ignored fields](#).

### Contiguous bit
