INFORMATION IN THIS DOCUMENT IS PROVIDED IN CONNECTION WITH INTEL PRODUCTS. NO LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE, TO ANY INTELLECTUAL PROPERTY RIGHTS IS GRANTED BY THIS DOCUMENT. EXCEPT AS PROVIDED IN INTEL'S TERMS AND CONDITIONS OF SALE FOR SUCH PRODUCTS, INTEL ASSUMES NO LIABILITY WHATSOEVER, AND INTEL DISCLAIMS ANY EXPRESS OR IMPLIED WARRANTY, RELATING TO SALE AND/OR USE OF INTEL PRODUCTS INCLUDING LIABILITY OR WARRANTIES RELATING TO FITNESS FOR A PARTICULAR PURPOSE, MERCHANTABILITY, OR INFRINGEMENT OF ANY PATENT, COPYRIGHT OR OTHER INTELLECTUAL PROPERTY RIGHT. INTEL PRODUCTS ARE NOT INTENDED FOR USE IN MEDICAL, LIFE SAVING, OR LIFE SUSTAINING APPLICATIONS.

Intel may make changes to specifications and product descriptions at any time, without notice.

Developers must not rely on the absence or characteristics of any features or instructions marked "reserved" or "undefined." Improper use of reserved or undefined features or instructions may cause unpredictable behavior or failure in developer's software code when running on an Intel processor. Intel reserves these features or instructions for future definition and shall have no responsibility whatsoever for conflicts or incompatibilities arising from their unauthorized use.

The Intel® 64 architecture processors may contain design defects or errors known as errata. Current characterized errata are available on request.

Hyper-Threading Technology requires a computer system with an Intel® processor supporting Hyper-Threading Technology and an HT Technology enabled chipset, BIOS and operating system. Performance will vary depending on the specific hardware and software you use. For more information, see <http://www.intel.com/technology/hyperthread/index.htm>; including details on which processors support HT Technology.

Intel® Virtualization Technology requires a computer system with an enabled Intel® processor, BIOS, virtual machine monitor (VMM) and for some uses, certain platform software enabled for it. Functionality, performance or other benefits will vary depending on hardware and software configurations. Intel® Virtualization Technology-enabled BIOS and VMM applications are currently in development.

64-bit computing on Intel architecture requires a computer system with a processor, chipset, BIOS, operating system, device drivers and applications enabled for Intel® 64 architecture. Processors will not operate (including 32-bit operation) without an Intel® 64 architecture-enabled BIOS. Performance will vary depending on your hardware and software configurations. Consult with your system vendor for more information.

Intel, Pentium, Intel Atom, Intel Xeon, Intel NetBurst, Intel Core, Intel Core Solo, Intel Core Duo, Intel Core 2 Duo, Intel Core 2 Extreme, Intel Pentium D, Itanium, Intel SpeedStep, MMX, and VTune are trademarks or registered trademarks of Intel Corporation or its subsidiaries in the United States and other countries.

## CHAPTER 1

### INTEL® ADVANCED VECTOR EXTENSIONS

|       |  |     |
|-------|--|-----|
| 1.1   | About This Document .....  | 1-1 |
| 1.2   | Overview .....   | 1-1 |
| 1.3   | Intel® Advanced Vector Extensions Architecture Overview .....            | 1-2 |
| 1.3.1 | 256-Bit Wide SIMD Register Support .....                                 | 1-2 |
| 1.3.2 | Instruction Syntax Enhancements .....                                    | 1-3 |
| 1.3.3 | VEX Prefix Instruction Encoding Support .....                            | 1-4 |
| 1.4   | Functional Overview .....  | 1-4 |
| 1.4.1 | 256-bit Floating-Point Arithmetic Processing Enhancements .....          | 1-5 |
| 1.4.2 | 256-bit Non-Arithmetic Instruction Enhancements .....                    | 1-5 |
| 1.4.3 | Arithmetic Primitives for 128-bit Vector and Scalar processing .....     | 1-6 |
| 1.4.4 | Non-Arithmetic Primitives for 128-bit Vector and Scalar Processing ..... | 1-6 |
| 1.5   | General Encryption and Cryptographic Processing .....                    | 1-7 |

## CHAPTER 2

### APPLICATION PROGRAMMING MODEL

|       |  |      |
|-------|--|------|
| 2.1   | Detection of PCLMULQDQ and AES Instructions .....                                      | 2-1  |
| 2.2   | Detection of AVX and FMA Instructions .....  | 2-1  |
| 2.2.1 | Detection of FMA .....   | 2-3  |
| 2.2.2 | Detection of VEX-Encoded AES and VPCLMULQDQ .....                                      | 2-4  |
| 2.3   | Fused-Multiply-ADD (FMA) Numeric Behavior .....  | 2-6  |
| 2.3.1 | FMA Instruction Operand Order and Arithmetic Behavior .....                            | 2-10 |
| 2.4   | Accessing YMM Registers .....  | 2-11 |
| 2.5   | Memory alignment .....   | 2-12 |
| 2.6   | SIMD floating-point Exceptions .....   | 2-14 |
| 2.7   | Instruction Exception Specification .....  | 2-14 |
| 2.7.1 | Exceptions Type 1 (Aligned memory reference) .....                                     | 2-20 |
| 2.7.2 | Exceptions Type 2 (>=16 Byte Memory Reference, Unaligned) .....                        | 2-21 |
| 2.7.3 | Exceptions Type 3 (<16 Byte memory argument) .....                                     | 2-22 |
| 2.7.4 | Exceptions Type 4 (>=16 Byte mem arg no alignment, no floating-point exceptions) ..... | 2-23 |
| 2.7.5 | Exceptions Type 5 (<16 Byte mem arg and no FP exceptions) .....                        | 2-24 |
| 2.7.6 | Exceptions Type 6 (VEX-Encoded Instructions Without Legacy SSE Analogues) .....        | 2-25 |
| 2.7.7 | Exceptions Type 7 (No FP exceptions, no memory arg) .....                              | 2-26 |
| 2.7.8 | Exceptions Type 8 (AVX and no memory argument) .....                                   | 2-27 |
| 2.7.9 | Exception Type 11 (VEX-only, mem arg no AC, floating-point exceptions) .....           | 2-28 |
| 2.8   | Programming Considerations with 128-bit SIMD Instructions .....                        | 2-28 |
| 2.8.1 | Clearing Upper YMM State Between AVX and Legacy SSE Instructions .....                 | 2-29 |
| 2.8.2 | Using AVX 128-bit Instructions Instead of Legacy SSE instructions .....                | 2-30 |
| 2.8.3 | Unaligned Memory Access and Buffer Size Management .....                               | 2-30 |
| 2.9   | CPUID Instruction .....  | 2-31 |
|       | CPUID—CPU Identification .....   | 2-31 |

# CHAPTER 3

## SYSTEM PROGRAMMING MODEL

- 3.1 YMM State, VEX Prefix and Supported Operating Modes ..... 3-1
- 3.2 YMM State Management ..... 3-2
  - 3.2.1 Detection of YMM State Support..... 3-2
  - 3.2.2 Enabling of YMM State ..... 3-2
  - 3.2.3 Enabling of SIMD Floating-Exception Support ..... 3-3
  - 3.2.4 The Layout of XSAVE Area ..... 3-4
  - 3.2.5 XSAVE/XRSTOR Interaction with YMM State and MXCSR..... 3-5
  - 3.2.6 Processor Extended State Save Optimization and XSAVEOPT ..... 3-7
    - 3.2.6.1 XSAVEOPT Usage Guidelines ..... 3-8
- 3.3 Reset Behavior ..... 3-9
- 3.4 Emulation..... 3-9
- 3.5 Writing AVX floating-point exception handlers..... 3-9

# CHAPTER 4

## INSTRUCTION FORMAT

- 4.1 Instruction Formats ..... 4-1
  - 4.1.1 VEX and the LOCK prefix ..... 4-2
  - 4.1.2 VEX and the 66H, F2H, and F3H prefixes..... 4-2
  - 4.1.3 VEX and the REX prefix ..... 4-2
  - 4.1.4 The VEX Prefix ..... 4-2
    - 4.1.4.1 VEX Byte 0, bits[7:0]..... 4-6
    - 4.1.4.2 VEX Byte 1, bit [7] - ‘R’ ..... 4-6
    - 4.1.4.3 3-byte VEX byte 1, bit[6] - ‘X’..... 4-6
    - 4.1.4.4 3-byte VEX byte 1, bit[5] - ‘B’..... 4-6
    - 4.1.4.5 3-byte VEX byte 2, bit[7] - ‘W’ ..... 4-6
    - 4.1.4.6 2-byte VEX Byte 1, bits[6:3] and 3-byte VEX Byte 2, bits [6:3]- ‘vvvv’ the Source or dest Register Specifier ..... 4-7
  - 4.1.5 Instruction Operand Encoding and VEX.vvvv, ModR/M..... 4-8
    - 4.1.5.1 3-byte VEX byte 1, bits[4:0] - “m-mmmm” ..... 4-9
    - 4.1.5.2 2-byte VEX byte 1, bit[2], and 3-byte VEX byte 2, bit [2]- “L”..... 4-10
    - 4.1.5.3 2-byte VEX byte 1, bits[1:0], and 3-byte VEX byte 2, bits [1:0]- “pp” ..... 4-10
  - 4.1.6 The Opcode Byte ..... 4-11
  - 4.1.7 The MODRM, SIB, and Displacement Bytes..... 4-11
  - 4.1.8 The Third Source Operand (Immediate Byte)..... 4-11
  - 4.1.9 AVX Instructions and the Upper 128-bits of YMM registers ..... 4-11
    - 4.1.9.1 Vector Length Transition and Programming Considerations ..... 4-11
  - 4.1.10 AVX Instruction Length ..... 4-12

# CHAPTER 5

## INSTRUCTION SET REFERENCE

- 5.1 Interpreting Instruction Reference Pages ..... 5-1
  - 5.1.1 Instruction Format ..... 5-1
    - ADDSD- ADD Scalar Double-Precision Floating-Point Values (THIS IS AN EXAMPLE) . 5-2
  - 5.1.2 Opcode Column in the Instruction Summary Table ..... 5-2
  - 5.1.3 Instruction Column in the Instruction Summary Table ..... 5-5

|         |   |       |
|---------|---|-------|
| 5.1.4   | Operand Encoding column in the Instruction Summary Table .....  | 5-5   |
| 5.1.5   | 64/32 bit Mode Support column in the Instruction Summary Table .....  | 5-5   |
| 5.1.6   | CPUID Support column in the Instruction Summary Table .....   | 5-6   |
| 5.2     | AES Transformations and Data Structure .....  | 5-6   |
| 5.2.1   | Little-Endian Architecture and Big-Endian Specification (FIPS 197) .....  | 5-6   |
| 5.2.1.1 | AES Data Structure in Intel 64 Architecture .....   | 5-7   |
| 5.2.2   | AES Transformations and Functions .....   | 5-9   |
| 5.3     | Summary of Terms .....  | 5-13  |
| 5.4     | Instruction SET Reference .....   | 5-14  |
|         | ADDPD - Add Packed Double Precision Floating-Point Values .....   | 5-15  |
|         | ADDPSS- Add Packed Single Precision Floating-Point Values .....   | 5-17  |
|         | ADDSD- Add Scalar Double Precision Floating-Point Values .....  | 5-19  |
|         | ADDSS- Add Scalar Single Precision Floating-Point Values .....  | 5-21  |
|         | ADDSUBPD- Packed Double FP Add/Subtract .....   | 5-23  |
|         | ADDSUBPS- Packed Single FP Add/Subtract .....   | 5-25  |
|         | AESENC/AESENC- Perform One Round of an AES Encryption Flow .....  | 5-27  |
|         | AESDEC/AESDECLAST- Perform One Round of an AES Decryption Flow .....  | 5-30  |
|         | AESIMC- Perform the AES InvMixColumn Transformation .....   | 5-33  |
|         | AESKEYGENASSIST - AES Round Key Generation Assist .....   | 5-35  |
|         | ANDPD- Bitwise Logical AND of Packed Double Precision Floating-Point Values .....   | 5-37  |
|         | ANDPS- Bitwise Logical AND of Packed Single Precision Floating-Point Values .....   | 5-39  |
|         | ANDNPD- Bitwise Logical AND NOT of Packed Double Precision Floating-Point<br>Values .....                                 | 5-41  |
|         | ANDNPS- Bitwise Logical AND NOT of Packed Single Precision Floating-Point<br>Values .....                                 | 5-43  |
|         | BLENDPD- Blend Packed Double Precision Floating-Point Values .....  | 5-45  |
|         | BLENDPS- Blend Packed Single Precision Floating-Point Values .....  | 5-47  |
|         | BLENDVPD- Blend Packed Double Precision Floating-Point Values .....   | 5-50  |
|         | BLENDVPS- Blend Packed Single Precision Floating-Point Values .....   | 5-53  |
|         | VBROADCAST- Load with Broadcast .....   | 5-56  |
|         | CMPPD- Compare Packed Double-Precision Floating-Point Values .....  | 5-60  |
|         | CMPPS- Compare Packed Single-Precision Floating-Point Values .....  | 5-69  |
|         | CMPSD- Compare Scalar Double-Precision Floating-Point Values .....  | 5-76  |
|         | CMPSS- Compare Scalar Single-Precision Floating-Point Values .....  | 5-81  |
|         | COMISD- Compare Scalar Ordered Double-Precision Floating-Point Values and<br>Set EFLAGS .....                             | 5-86  |
|         | COMISS- Compare Scalar Ordered Single-Precision Floating-Point Values and<br>Set EFLAGS .....                             | 5-88  |
|         | CVTDQ2PD- Convert Packed Doubleword Integers to Packed Double-Precision<br>Floating-Point Values .....                    | 5-90  |
|         | CVTDQ2PS- Convert Packed Doubleword Integers to Packed Single-Precision<br>Floating-Point Values .....                    | 5-92  |
|         | CVTPD2DQ- Convert Packed Double-Precision Floating-point values to Packed<br>Doubleword Integers .....                    | 5-94  |
|         | CVTPD2PS- Convert Packed Double-Precision Floating-point values to Packed<br>Single-Precision Floating-Point Values ..... | 5-97  |
|         | CVTPS2DQ- Convert Packed Single Precision Floating-Point Values to Packed<br>Signed Doubleword Integer Values .....       | 5-100 |

|   |       |
|---|-------|
| CVTPS2PD- Convert Packed Single Precision Floating-point values to Packed Double Precision Floating-Point Values .....            | 5-102 |
| CVTSD2SI- Convert Scalar Double-Precision Floating-Point Value to Doubleword Integer .....  | 5-105 |
| CVTSD2SS- Convert Scalar Double-Precision Floating-Point Value to Scalar Single-Precision Floating-Point Value .....              | 5-107 |
| CVTSI2SD- Convert Doubleword Integer to Scalar Double-Precision Floating-Point Value .....  | 5-109 |
| CVTSI2SS- Convert Doubleword Integer to Scalar Single-Precision Floating-Point Value .....  | 5-111 |
| CVTSS2SD- Convert Scalar Single-Precision Floating-Point Value to Scalar Double-Precision Floating-Point Value .....              | 5-114 |
| CVTSS2SI- Convert Scalar Single-Precision Floating-Point Value to Doubleword Integer .....  | 5-116 |
| CVTTPD2DQ- Convert with Truncation Packed Double-Precision Floating-point values to Packed Doubleword Integers .....              | 5-118 |
| CVTTPS2DQ- Convert with Truncation Packed Single Precision Floating-Point Values to Packed Signed Doubleword Integer Values ..... | 5-121 |
| CVTTSD2SI- Convert with Truncation Scalar Double-Precision Floating-Point Value to Signed Doubleword Integer .....                | 5-123 |
| CVTTSS2SI- Convert with Truncation Scalar Single-Precision Floating-Point Value to Doubleword Integer .....                       | 5-125 |
| DIVPD- Divide Packed Double-Precision Floating-Point Values .....   | 5-127 |
| DIVPS- Divide Packed Single-Precision Floating-Point Values .....   | 5-129 |
| DIVSD- Divide Scalar Double-Precision Floating-Point Values .....   | 5-131 |
| DIVSS- Divide Scalar Single-Precision Floating-Point Values .....   | 5-133 |
| DPPD- Dot Product of Packed Double-Precision Floating-Point Values .....  | 5-135 |
| DPPS- Dot Product of Packed Single-Precision Floating-Point Values .....  | 5-137 |
| VEXTRACTF128- Extract packed floating-point values .....  | 5-140 |
| EXTRACTPS- Extract packed floating-point values .....   | 5-142 |
| HADDPD- Add Horizontal Double Precision Floating-Point Values .....   | 5-144 |
| HADDPS- Add Horizontal Single Precision Floating-Point Values .....   | 5-147 |
| HSUBPD- Subtract Horizontal Double Precision Floating-Point Values .....  | 5-150 |
| HSUBPS- Subtract Horizontal Single Precision Floating-Point Values .....  | 5-153 |
| VINSERTF128- Insert packed floating-point values .....  | 5-156 |
| INSERTPS- Insert Scalar Single Precision Floating-Point Value .....   | 5-158 |
| LDDQU- Move Unaligned Integer .....   | 5-162 |
| VLDMXCSR—Load MXCSR Register .....  | 5-164 |
| MASKMOVDQU- Store Selected Bytes of Double Quadword with NT Hint .....  | 5-166 |
| VMASKMOV- Conditional SIMD Packed Loads and Stores .....  | 5-169 |
| MAXPD- Maximum of Packed Double Precision Floating-Point Values .....   | 5-173 |
| MAXPS- Maximum of Packed Single Precision Floating-Point Values .....   | 5-176 |
| MAXSD- Return Maximum Scalar Double-Precision Floating-Point Value .....  | 5-179 |
| MAXSS- Return Maximum Scalar Single-Precision Floating-Point Value .....  | 5-181 |
| MINPD- Minimum of Packed Double Precision Floating-Point Values .....   | 5-183 |
| MINPS- Minimum of Packed Single Precision Floating-Point Values .....   | 5-186 |
| MINSD- Return Minimum Scalar Double-Precision Floating-Point Value .....  | 5-189 |

|  |       |
|--|-------|
| MINSS- Return Minimum Scalar Single-Precision Floating-Point Value .....                       | 5-191 |
| MOVAPD- Move Aligned Packed Double-Precision Floating-Point Values .....                       | 5-193 |
| MOVAPS- Move Aligned Packed Single-Precision Floating-Point Values .....                       | 5-196 |
| MOVQ/MOVQ- Move Doubleword and Quadword .....  | 5-199 |
| MOVQ- Move Quadword .....  | 5-202 |
| MOVDDUP- Replicate Double FP Values .....  | 5-205 |
| MOVDDQA- Move Aligned Packed Integer Values .....  | 5-207 |
| MOVDDQU- Move Unaligned Packed Integer Values .....  | 5-210 |
| MOVHLPS - Move Packed Single-Precision Floating-Point Values High to Low ....                  | 5-213 |
| MOVHPD- Move High Packed Double-Precision Floating-Point Values .....                          | 5-215 |
| MOVHPS- Move High Packed Single-Precision Floating-Point Values .....                          | 5-217 |
| MOVLHPS - Move Packed Single-Precision Floating-Point Values Low to High ....                  | 5-219 |
| MOVLPD- Move Low Packed Double-Precision Floating-Point Values .....                           | 5-221 |
| MOVLPS- Move Low Packed Single-Precision Floating-Point Values .....                           | 5-223 |
| MOVMSKPD- Extract Double-Precision Floating-Point Sign mask .....                              | 5-225 |
| MOVMSKPS- Extract Single-Precision Floating-Point Sign mask .....                              | 5-227 |
| MOVNTDQ- Store Packed Integers Using Non-Temporal Hint .....                                   | 5-229 |
| MOVNTDQA- Load Double Quadword Non-Temporal Aligned Hint .....                                 | 5-231 |
| MOVNTPD- Store Packed Double-Precision Floating-Point Values Using Non-<br>Temporal Hint ..... | 5-233 |
| MOVNTPS- Store Packed Single-Precision Floating-Point Values Using Non-<br>Temporal Hint ..... | 5-235 |
| MOVSD- Move or Merge Scalar Double-Precision Floating-Point Value .....                        | 5-237 |
| MOVSHDUP- Replicate Single FP Values .....   | 5-240 |
| MOVSLDUP- Replicate Single FP Values .....   | 5-243 |
| MOVSS- Move or Merge Scalar Single-Precision Floating-Point Value .....                        | 5-246 |
| MOVUPD- Move Unaligned Packed Double-Precision Floating-Point Values .....                     | 5-249 |
| MOVUPS- Move Unaligned Packed Single-Precision Floating-Point Values .....                     | 5-252 |
| MPSADBW - Multiple Sum of Absolute Differences .....   | 5-255 |
| MULPD- Multiply Packed Double Precision Floating-Point Values .....                            | 5-260 |
| MULPS- Multiply Packed Single Precision Floating-Point Values .....                            | 5-262 |
| MULSD- Multiply Scalar Double-Precision Floating-Point Values .....                            | 5-264 |
| MULSS- Multiply Scalar Single-Precision Floating-Point Values .....                            | 5-266 |
| ORPD- Bitwise Logical OR of Packed Double Precision Floating-Point Values ....                 | 5-268 |
| ORPS- Bitwise Logical OR of Packed Single Precision Floating-Point Values ....                 | 5-270 |
| PABSB/PABSW/PABSD - Packed Absolute Value .....  | 5-272 |
| PACKSSWB/PACKSSDW- Pack with Signed Saturation .....   | 5-275 |
| PACKUSWB/PACKUSDW- Pack with Unsigned Saturation .....   | 5-279 |
| PADDB/PADDW/PADDD/PADDQ- Add Packed Integers .....   | 5-282 |
| PADDSB/PADDSW- Add Packed Signed Integers with Signed Saturation .....                         | 5-286 |
| PADDUSB/PADDUSW- Add Packed Unsigned Integers with Unsigned Saturation ..                      | 5-289 |
| PALIGNR - Byte Align .....   | 5-292 |
| PAND- Logical AND .....  | 5-294 |
| PANDN- Logical AND NOT .....   | 5-296 |
| PAVGB/PAVGW - Average Packed Integers .....  | 5-298 |
| PBLENDVB - Variable Blend Packed Bytes .....   | 5-300 |
| PBLENDW - Blend Packed Words .....   | 5-304 |

|   |       |
|---|-------|
| PCLMULQDQ - Carry-Less Multiplication Quadword                            | 5-307 |
| PCMPEQB/PCMPEQW/PCMPEQD/PCMPEQQ- Compare Packed Integers for Equality     | 5-311 |
| PCMPESTRI - Packed Compare Explicit Length Strings, Return Index          | 5-315 |
| PCMPESTRM - Packed Compare Explicit Length Strings, Return Mask           | 5-317 |
| PCMPGTB/PCMPGTW/PCMPGTD/PCMPGTQ- Compare Packed Integers for Greater Than | 5-319 |
| PCMPISTRI - Packed Compare Implicit Length Strings, Return Index          | 5-323 |
| PCMPISTRM - Packed Compare Implicit Length Strings, Return Mask           | 5-325 |
| VPERMILPD- Permute Double-Precision Floating-Point Values                 | 5-327 |
| VPERMILPS- Permute Single-Precision Floating-Point Values                 | 5-331 |
| VPERM2F128- Permute Floating-Point Values                                 | 5-335 |
| PEXTRB/PEXTRW/PEXTRD/PEXTRQ- Extract Integer                              | 5-337 |
| PHADDW/PHADDD - Packed Horizontal Add                                     | 5-341 |
| PHADDSW - Packed Horizontal Add with Saturation                           | 5-344 |
| PHMINPOSUW - Horizontal Minimum and Position                              | 5-346 |
| PHSUBW/PHSUBD - Packed Horizontal Subtract                                | 5-348 |
| PHSUBSW - Packed Horizontal Subtract with Saturation                      | 5-351 |
| PINSRB/PINSRW/PINSRD/PINSRQ- Insert Integer                               | 5-353 |
| PMADDWD- Multiply and Add Packed Integers                                 | 5-358 |
| PMADDUBSW- Multiply and Add Packed Integers                               | 5-360 |
| PMASXB/PMASXW/PMASXD- Maximum of Packed Signed Integers                   | 5-362 |
| PMASUB/PMASUW/PMASUD- Maximum of Packed Unsigned Integers                 | 5-366 |
| PMINSB/PMINSW/PMINSD- Minimum of Packed Signed Integers                   | 5-370 |
| PMINUB/PMINUW/PMINUD- Minimum of Packed Unsigned Integers                 | 5-374 |
| PMOVMASKB- Move Byte Mask   | 5-378 |
| PMOVSW - Packed Move with Sign Extend                                     | 5-380 |
| PMOVZX - Packed Move with Zero Extend                                     | 5-385 |
| PMULHUW - Multiply Packed Unsigned Integers and Store High Result         | 5-390 |
| PMULHRW - Multiply Packed Unsigned Integers with Round and Shift          | 5-392 |
| PMULHW - Multiply Packed Integers and Store High Result                   | 5-394 |
| PMULLW/PMULLD - Multiply Packed Integers and Store Low Result             | 5-396 |
| PMULUDQ - Multiply Packed Unsigned Doubleword Integers                    | 5-399 |
| PMULDQ - Multiply Packed Doubleword Integers                              | 5-401 |
| POR - Bitwise Logical Or  | 5-403 |
| PSADBW - Compute Sum of Absolute Differences                              | 5-405 |
| PSHUFB - Packed Shuffle Bytes   | 5-407 |
| PSHUFD - Shuffle Packed Doublewords                                       | 5-409 |
| PSHUFW - Shuffle Packed High Words  | 5-412 |
| PSHUFLW - Shuffle Packed Low Words  | 5-414 |
| PSIGNB/PSIGNW/PSIGND - Packed SIGN  | 5-416 |
| PSLLDQ - Byte Shift Left  | 5-420 |
| PSRLDQ - Byte Shift Right   | 5-422 |
| PSLLW/PSLLD/PSLLQ - Bit Shift Left  | 5-424 |
| PSRAW/PSRAD - Bit Shift Arithmetic Right                                  | 5-429 |
| PSRLW/PSRLD/PSRLQ - Shift Packed Data Right Logical                       | 5-433 |
| PTEST- Packed Bit Test  | 5-438 |

|  |       |
|--|-------|
| PSUBB/PSUBW/PSUBD/PSUBQ -Packed Integer Subtract .....   | 5-443 |
| PSUBSB/PSUBSW -Subtract Packed Signed Integers with Signed Saturation .....                                      | 5-447 |
| PSUBUSB/PSUBUSW -Subtract Packed Unsigned Integers with Unsigned Saturation .....                                | 5-450 |
| PUNPCKHBW/PUNPCKHWD/PUNPCKHDQ/PUNPCKHQDQ - Unpack High Data .....  | 5-453 |
| PUNPCKLBW/PUNPCKLWD/PUNPCKLDQ/PUNPCKLQDQ - Unpack Low Data .....   | 5-458 |
| PXOR - Exclusive Or .....  | 5-462 |
| RCPPS- Compute Approximate Reciprocals of Packed Single-Precision Floating-Point Values .....                    | 5-464 |
| RCPSS - Compute Reciprocal of Scalar Single-Precision Floating-Point Value .....                                 | 5-467 |
| RSQRTPS - Compute Approximate Reciprocals of Square Roots of Packed Single-Precision Floating-point Values ..... | 5-469 |
| RSQRTSS - Compute Reciprocal of Square Root of Scalar Single-Precision Floating-Point Value .....                | 5-472 |
| ROUNDPD- Round Packed Double-Precision Floating-Point Values .....   | 5-474 |
| ROUNDPS- Round Packed Single-Precision Floating-Point Values .....   | 5-478 |
| ROUNDSD - Round Scalar Double-Precision Value .....  | 5-481 |
| ROUNDSS - Round Scalar Single-Precision Value .....  | 5-483 |
| SHUFPD - Shuffle Packed Double Precision Floating-Point Values .....   | 5-485 |
| SHUFPS - Shuffle Packed Single Precision Floating-Point Values .....   | 5-488 |
| SQRTPD- Square Root of Double-Precision Floating-Point Values .....  | 5-491 |
| SQRTPS- Square Root of Single-Precision Floating-Point Values .....  | 5-493 |
| SQRTSD - Compute Square Root of Scalar Double-Precision Floating-Point Value .....                               | 5-495 |
| SQRTSS - Compute Square Root of Scalar Single-Precision Value .....  | 5-497 |
| VSTMXCSR—Store MXCSR Register State .....  | 5-499 |
| SUBPD- Subtract Packed Double Precision Floating-Point Values .....  | 5-500 |
| SUBPS- Subtract Packed Single Precision Floating-Point Values .....  | 5-502 |
| SUBSD- Subtract Scalar Double Precision Floating-Point Values .....  | 5-504 |
| SUBSS- Subtract Scalar Single Precision Floating-Point Values .....  | 5-506 |
| UCOMISD - Unordered Compare Scalar Double-Precision Floating-Point Values and Set EFLAGS .....                   | 5-508 |
| UCOMISS - Unordered Compare Scalar Single-Precision Floating-Point Values and Set EFLAGS .....                   | 5-510 |
| UNPCKHPD- Unpack and Interleave High Packed Double-Precision Floating-Point Values .....                         | 5-512 |
| UNPCKHPS- Unpack and Interleave High Packed Single-Precision Floating-Point Values .....                         | 5-514 |
| UNPCKLPD- Unpack and Interleave Low Packed Double-Precision Floating-Point Values .....                          | 5-517 |
| UNPCKLPS- Unpack and Interleave Low Packed Single-Precision Floating-Point Values .....                          | 5-519 |
| XORPD- Bitwise Logical XOR of Packed Double Precision Floating-Point Values ..                                   | 5-522 |
| XORPS- Bitwise Logical XOR of Packed Single Precision Floating-Point Values ...                                  | 5-524 |
| VZEROALL- Zero All YMM registers .....   | 5-526 |
| VZERoupper- Zero Upper bits of YMM registers .....   | 5-528 |
| XSAVEOPT—Save Processor Extended States Optimized .....  | 5-530 |

CHAPTER 6  
INSTRUCTION SET REFERENCE - FMA

6.1 FMA Instruction SET Reference ..... 6-1

- VFMAADD132PD/VFMAADD213PD/VFMAADD231PD - Fused Multiply-Add of Packed Double-Precision Floating-Point Values..... 6-2
- VFMAADD132PS/VFMAADD213PS/VFMAADD231PS - Fused Multiply-Add of Packed Single-Precision Floating-Point Values..... 6-6
- VFMAADD132SD/VFMAADD213SD/VFMAADD231SD - Fused Multiply-Add of Scalar Double-Precision Floating-Point Values..... 6-10
- VFMAADD132SS/VFMAADD213SS/VFMAADD231SS - Fused Multiply-Add of Scalar Single-Precision Floating-Point Values..... 6-13
- VFMAADDSUB132PD/VFMAADDSUB213PD/VFMAADDSUB231PD - Fused Multiply-Alternating Add/Subtract of Packed Double-Precision Floating-Point Values..... 6-16
- VFMAADDSUB132PS/VFMAADDSUB213PS/VFMAADDSUB231PS - Fused Multiply-Alternating Add/Subtract of Packed Single-Precision Floating-Point Values..... 6-20
- VFMSUBADD132PD/VFMSUBADD213PD/VFMSUBADD231PD - Fused Multiply-Alternating Subtract/Add of Packed Double-Precision Floating-Point Values..... 6-24
- VFMSUBADD132PS/VFMSUBADD213PS/VFMSUBADD231PS - Fused Multiply-Alternating Subtract/Add of Packed Single-Precision Floating-Point Values..... 6-28
- VFMSUB132PD/VFMSUB213PD/VFMSUB231PD - Fused Multiply-Subtract of Packed Double-Precision Floating-Point Values ..... 6-32
- VFMSUB132PS/VFMSUB213PS/VFMSUB231PS - Fused Multiply-Subtract of Packed Single-Precision Floating-Point Values ..... 6-36
- VFMSUB132SD/VFMSUB213SD/VFMSUB231SD - Fused Multiply-Subtract of Scalar Double-Precision Floating-Point Values ..... 6-40
- VFMSUB132SS/VFMSUB213SS/VFMSUB231SS - Fused Multiply-Subtract of Scalar Single-Precision Floating-Point Values..... 6-43
- VFNMADD132PD/VFNMADD213PD/VFNMADD231PD - Fused Negative Multiply-Add of Packed Double-Precision Floating-Point Values ..... 6-46
- VFNMADD132PS/VFNMADD213PS/VFNMADD231PS - Fused Negative Multiply-Add of Packed Single-Precision Floating-Point Values ..... 6-50
- VFNMADD132SD/VFNMADD213SD/VFNMADD231SD - Fused Negative Multiply-Add of Scalar Double-Precision Floating-Point Values ..... 6-54
- VFNMADD132SS/VFNMADD213SS/VFNMADD231SS - Fused Negative Multiply-Add of Scalar Single-Precision Floating-Point Values ..... 6-57
- VFNMMSUB132PD/VFNMMSUB213PD/VFNMMSUB231PD - Fused Negative Multiply-Subtract of Packed Double-Precision Floating-Point Values..... 6-60
- VFNMMSUB132PS/VFNMMSUB213PS/VFNMMSUB231PS - Fused Negative Multiply-Subtract of Packed Single-Precision Floating-Point Values..... 6-64
- VFNMMSUB132SD/VFNMMSUB213SD/VFNMMSUB231SD - Fused Negative Multiply-Subtract of Scalar Double-Precision Floating-Point Values..... 6-68
- VFNMMSUB132SS/VFNMMSUB213SS/VFNMMSUB231SS - Fused Negative Multiply-Subtract of Scalar Single-Precision Floating-Point Values..... 6-71

## CHAPTER 7 POST-32NM PROCESSOR INSTRUCTIONS

|       |   |      |
|-------|---|------|
| 7.1   | Overview .....  | 7-1  |
| 7.2   | CPUID Detection of New Instructions .....                                   | 7-1  |
| 7.3   | 16-Bit Floating-Point Data type Support .....                               | 7-3  |
| 7.3.1 | Half-Precision Floating-Point Conversion.....                               | 7-6  |
| 7.4   | Vector Instruction Exception Specification .....                            | 7-9  |
| 7.4.1 | Exception Type 11 (VEX-only, mem arg no AC, floating-point exceptions)..... | 7-10 |
| 7.5   | FS/GS base support for 64-bit Software .....                                | 7-10 |
| 7.6   | Using RDRAND Instruction and Intrinsic .....                                | 7-11 |
| 7.7   | Instruction Reference .....   | 7-12 |
|       | RDFSBASE/RDGSBASE—Read FS/GS Segment Base Register.....                     | 7-13 |
|       | RDRAND—Read Random Number.....  | 7-15 |
|       | WRFSBASE/wRGSBASE—Write FS/GS Segment Base Register .....                   | 7-18 |
|       | VCVTPH2PS - Convert 16-bit FP values to Single-Precision FP values .....    | 7-20 |
|       | VCVTPS2PH - Convert Single-Precision FP value to 16-bit FP value .....      | 7-23 |

## APPENDIX A Instruction Summary

## APPENDIX B OPCODE MAP

|         |  |      |
|---------|--|------|
| B.1     | Using Opcode Tables.....   | B-1  |
| B.2     | Key to Abbreviations .....   | B-2  |
| B.2.1   | Codes for Addressing Method .....                                  | B-2  |
| B.2.2   | Codes for Operand Type .....                                       | B-3  |
| B.2.3   | Register Codes .....   | B-4  |
| B.2.4   | Opcode Look-up Examples for One, Two, and Three-Byte Opcodes ..... | B-4  |
| B.2.4.1 | One-Byte Opcode Instructions .....                                 | B-5  |
| B.2.4.2 | Two-Byte Opcode Instructions .....                                 | B-6  |
| B.2.4.3 | Three-Byte Opcode Instructions.....                                | B-7  |
| B.2.4.4 | VEX Prefix Instructions .....                                      | B-7  |
| B.2.5   | Superscripts Utilized in Opcode Tables.....                        | B-8  |
| B.3     | One, Two, and THREE-Byte Opcode Maps.....                          | B-9  |
| B.4     | Opcode Extensions For One-Byte And Two-byte Opcodes .....          | B-20 |
| B.4.1   | Opcode Look-up Examples Using Opcode Extensions .....              | B-20 |
| B.4.2   | Opcode Extension Tables .....                                      | B-21 |
| B.5     | Escape Opcode Instructions .....                                   | B-23 |
| B.5.1   | Opcode Look-up Examples for Escape Instruction Opcodes.....        | B-23 |
| B.5.2   | Escape Opcode Instruction Tables .....                             | B-23 |
| B.5.2.1 | Escape Opcodes with D8 as First Byte.....                          | B-24 |
| B.5.2.2 | Escape Opcodes with D9 as First Byte.....                          | B-25 |
| B.5.2.3 | Escape Opcodes with DA as First Byte.....                          | B-26 |
| B.5.2.4 | Escape Opcodes with DB as First Byte.....                          | B-27 |
| B.5.2.5 | Escape Opcodes with DC as First Byte.....                          | B-28 |
| B.5.2.6 | Escape Opcodes with DD as First Byte.....                          | B-29 |
| B.5.2.7 | Escape Opcodes with DE as First Byte.....                          | B-30 |

**CONTENTS**

B.5.2.8      Escape Opcodes with DF As First Byte ..... B-31

# TABLES

|      | PAGE  |
|------|---|
| 2-1  | Rounding behavior of Zero Result in FMA Operation . . . . . 2-7                       |
| 2-2  | FMA Numeric Behavior . . . . . 2-8  |
| 2-3  | Alignment Faulting Conditions when Memory Access is Not Aligned. . . . . 2-13         |
| 2-4  | Instructions Requiring Explicitly Aligned Memory . . . . . 2-13                       |
| 2-5  | Instructions Not Requiring Explicit Memory Alignment . . . . . 2-14                   |
| 2-6  | Exception class description . . . . . 2-15  |
| 2-7  | Instructions in each Exception Class. . . . . 2-16                                    |
| 2-8  | #UD Exception and VEX.W=1 Encoding. . . . . 2-18                                      |
| 2-9  | #UD Exception and VEX.L Field Encoding . . . . . 2-19                                 |
| 2-10 | Type 1 Class Exception Conditions . . . . . 2-20                                      |
| 2-11 | Type 2 Class Exception Conditions . . . . . 2-21                                      |
| 2-12 | Type 3 Class Exception Conditions . . . . . 2-22                                      |
| 2-13 | Type 4 Class Exception Conditions . . . . . 2-23                                      |
| 2-14 | Type 5 Class Exception Conditions . . . . . 2-24                                      |
| 2-15 | Type 6 Class Exception Conditions . . . . . 2-25                                      |
| 2-16 | Type 7 Class Exception Conditions . . . . . 2-26                                      |
| 2-17 | Type 8 Class Exception Conditions . . . . . 2-27                                      |
| 2-18 | Type 11 Class Exception Conditions. . . . . 2-28                                      |
| 2-19 | Information Returned by CPUID Instruction. . . . . 2-32                               |
| 2-20 | Highest CPUID Source Operand for Intel 64 and IA-32 Processors . . . . . 2-42         |
| 2-21 | Processor Type Field. . . . . 2-44  |
| 2-22 | Feature Information Returned in the ECX Register. . . . . 2-46                        |
| 2-23 | More on Feature Information Returned in the EDX Register . . . . . 2-50               |
| 2-24 | Encoding of Cache and TLB Descriptors . . . . . 2-52                                  |
| 2-25 | Structured Extended Feature Leaf, Function 0, EBX Register. . . . . 2-57              |
| 2-26 | Processor Brand String Returned with Pentium 4 Processor. . . . . 2-60                |
| 2-27 | Mapping of Brand Indices; and Intel 64 and IA-32 Processor Brand Strings . . . . 2-62 |
| 3-1  | XFEATURE_ENABLED_MASK and Processor State Components . . . . . 3-3                    |
| 3-2  | CR4 bits for AVX New Instructions technology support. . . . . 3-3                     |
| 3-3  | Layout of XSAVE Area For Processor Supporting YMM State . . . . . 3-4                 |
| 3-4  | XSAVE Header Format . . . . . 3-4   |
| 3-5  | XSAVE Save Area Layout for YMM State (Ext_Save_Area_2) . . . . . 3-5                  |
| 3-6  | XRSTOR Action on MXCSR, XMM Registers, YMM Registers. . . . . 3-5                     |
| 3-7  | Processor Supplied Init Values XRSTOR May Use . . . . . 3-6                           |
| 3-8  | XSAVE Action on MXCSR, XMM, YMM Register . . . . . 3-7                                |
| 4-1  | VEX.vvvv to register name mapping . . . . . 4-8                                       |
| 4-2  | Instructions with a VEX.vvvv destination . . . . . 4-9                                |
| 4-3  | VEX.m-mmmm interpretation . . . . . 4-10  |
| 4-4  | VEX.L interpretation . . . . . 4-10   |
| 4-5  | VEX.pp interpretation . . . . . 4-11  |
| 5-1  | Byte and 32-bit Word Representation of a 128-bit State. . . . . 5-8                   |
| 5-2  | Matrix Representation of a 128-bit State . . . . . 5-8                                |

# CHAPTER 1

## INTEL® ADVANCED VECTOR EXTENSIONS

---

### 1.1 ABOUT THIS DOCUMENT

This document describes the software programming interfaces of several vector SIMD instruction extensions of the Intel® 64 architecture that will be introduced starting with Intel 64 processors built on 32nm process technology. The instruction set extensions covered in this document, with respect to availability in different processor generations, is referred to by the following categories:

- General-purpose encryption and AES: 128-bit SIMD extensions targeted to accelerate high-speed block encryption and cryptographic processing using the Advanced Encryption Standard.
- Intel® Advanced Vector Extensions (AVX) introduces 256-bit vector processing capability and includes two components to be introduced on Intel processor generations built from 32nm process and beyond:
  - The first generation Intel AVX provides 256-bit SIMD register support, 256-bit vector floating-point instructions, enhancements to 128-bit SIMD instructions, support for three and four operand syntax.
  - FMA is a future extension of Intel AVX, FMA provides floating-point, fused multiply-add instructions supporting 256-bit and 128-bit SIMD vectors.

Chapter 1 provides an overview of these instruction set extensions. Chapter 2 describes the application programming environment. Chapter 3 describes system programming requirements needed to support 256-bit registers. Chapter 4 describes the architectural extensions of Intel 64 instruction encoding format that support 256-bit registers, three and four operand syntax. Chapter 5 provides detailed instruction reference for AVX and encryption/AES instructions. Chapter 6 provides detailed instruction reference for FMA instructions.

### 1.2 OVERVIEW

Intel® Advanced Vector Extensions extend beyond the capabilities and programming environment over those of multiple generations of Streaming SIMD Extensions. Intel AVX address the continued need for vector floating-point performance in mainstream scientific and engineering numerical applications, visual processing, recognition, data-mining/synthesis, gaming, physics, cryptography and other areas of applications. Intel AVX is designed to facilitate efficient implementation by wide spectrum of software architectures of varying degrees of thread parallelism, and data vector lengths. Intel AVX offers the following benefits:

- efficient building blocks for applications targeted across all segments of computing platforms.

- significant increase in floating-point performance density with good power efficiency over previous generations of 128-bit SIMD instruction set extensions,
- scalable performance with multi-core processor capability.

Intel AVX also establishes a foundation for future evolution in both instruction set functionality and vector lengths by introducing an efficient instruction encoding scheme, three and four operand instruction syntax, supporting load and store masking, etc.

Intel Advanced Vector Extensions offers comprehensive architectural enhancements and functional enhancements in arithmetic as well as data processing primitives. Section 1.3 summarizes the architectural enhancement of AVX. Functional overview of AVX and FMA instructions are summarized in Section 1.4. General-purpose encryption and AES instructions follow the existing architecture of 128-bit SIMD instruction sets like SSE4 and its predecessors, Section 1.5 provides a short summary.

### 1.3 INTEL® ADVANCED VECTOR EXTENSIONS ARCHITECTURE OVERVIEW

Intel AVX has many similarities to the SSE and double-precision floating-point portions of SSE2. However, Intel AVX introduces the following architectural enhancements:

- Support for 256-bit wide vectors and SIMD register set. 256-bit register state is managed by Operating System using XSAVE/XRSTOR instructions introduced in 45 nm Intel 64 processors (see *IA-32 Intel® Architecture Software Developer's Manual, Volumes 2B and 3A*).
- Instruction syntax support for generalized three-operand syntax to improve instruction programming flexibility and efficient encoding of new instruction extensions.
- Enhancement of legacy 128-bit SIMD instruction extensions to support three-operand syntax and to simplify compiler vectorization of high-level language expressions.
- Instruction encoding format using a new prefix (referred to as VEX) to provide compact, efficient encoding for three-operand syntax, vector lengths, compaction of SIMD prefixes and REX functionality.
- FMA extensions and enhanced floating-point compare instructions add support for IEEE-754-2008 standard.

#### 1.3.1 256-Bit Wide SIMD Register Support

Intel AVX introduces support for 256-bit wide SIMD registers (YMM0-YMM7 in operating modes that are 32-bit or less, YMM0-YMM15 in 64-bit mode). The lower 128-bits of the YMM registers are aliased to the respective 128-bit XMM registers.

### 1.3.2 Instruction Syntax Enhancements

Intel AVX employs an instruction encoding scheme using a new prefix (known as “VEX” prefix). Instruction encoding using the VEX prefix can directly encode a register operand within the VEX prefix. This support two new instruction syntax in Intel 64 architecture:

- A non-destructive operand (in a three-operand instruction syntax): The non-destructive source reduces the number of registers, register-register copies and explicit load operations required in typical SSE loops, reduces code size, and improves micro-fusion opportunities.
- A third source operand (in a four-operand instruction syntax) via the upper 4 bits in an 8-bit immediate field. Support for the third source operand is defined for selected instructions (e.g. VBLENDVPD, VBLENDVPS, PBLENDVB).

Two-operand instruction syntax previously expressed as

```
ADDPS xmm1, xmm2/m128
```

now can be expressed in three-operand syntax as

```
VADDPS xmm1, xmm2, xmm3/m128
```

In four-operand syntax, the extra register operand is encoded in the immediate byte.

Note SIMD instructions supporting three-operand syntax but processing only 128-bits of data are considered part of the 256-bit SIMD instruction set extensions of AVX, because bits 255:128 of the destination register are zeroed by the processor.

### 1.3.3 VEX Prefix Instruction Encoding Support

Intel AVX introduces a new prefix, referred to as VEX, in the Intel 64 and IA-32 instruction encoding format. Instruction encoding using the VEX prefix provides the following capabilities:

- Direct encoding of a register operand within VEX. This provides instruction syntax support for non-destructive source operand.
- Efficient encoding of instruction syntax operating on 128-bit and 256-bit register sets.
- Compaction of REX prefix functionality: The equivalent functionality of the REX prefix is encoded within VEX.
- Compaction of SIMD prefix functionality and escape byte encoding: The functionality of SIMD prefix (66H, F2H, F3H) on opcode is equivalent to an opcode extension field to introduce new processing primitives. This functionality is replaced by a more compact representation of opcode extension within the VEX prefix. Similarly, the functionality of the escape opcode byte (0FH) and two-byte escape (0F38H, 0F3AH) are also compacted within the VEX prefix encoding.
- Most VEX-encoded SIMD numeric and data processing instruction semantics with memory operand have relaxed memory alignment requirements than instructions encoded using SIMD prefixes (see Section 2.5).

VEX prefix encoding applies to SIMD instructions operating on YMM registers, XMM registers, and in some cases with a general-purpose register as one of the operand. VEX prefix is not supported for instructions operating on MMX or x87 registers. Details of VEX prefix and instruction encoding are discussed in Chapter 4.

## 1.4 FUNCTIONAL OVERVIEW

Intel AVX and FMA provide comprehensive functional improvements over previous generations of SIMD instruction extensions. The functional improvements include:

- 256-bit floating-point arithmetic primitives: AVX enhances existing 128-bit floating-point arithmetic instructions with 256-bit capabilities for floating-point processing. FMA provides additional set of 256-bit floating-point processing capabilities with a rich set of fused-multiply-add and fused multiply-subtract primitives.
- Enhancements for flexible SIMD data movements: AVX provides a number of new data movement primitives to enable efficient SIMD programming in relation to loading non-unit-strided data into SIMD registers, intra-register SIMD data manipulation, conditional expression and branch handling, etc. Enhancements

for SIMD data movement primitives cover 256-bit and 128-bit vector floating-point data, and across 128-bit integer SIMD data processing using VEX-encoded instructions.

Several key categories of functional improvements in AVX and FMA are summarized in the following subsections.

### 1.4.1 256-bit Floating-Point Arithmetic Processing Enhancements

Intel AVX provides 35 256-bit floating-point arithmetic instructions. The arithmetic operations cover add, subtract, multiply, divide, square-root, compare, max, min, round, etc., on single-precision and double-precision floating-point data.

The enhancement in AVX on floating-point compare operation provides 32 conditional predicates to improve programming flexibility in evaluating conditional expressions.

FMA provides 36 256-bit floating-point instructions to perform computation on 256-bit vectors. The arithmetic operations cover fused multiply-add, fused multiply-subtract, fused multiply add/subtract interleave, signed-reversed multiply on fused multiply-add and multiply-subtract.

### 1.4.2 256-bit Non-Arithmetic Instruction Enhancements

Intel AVX provides new primitives for handling data movement within 256-bit floating-point vectors and promotes many 128-bit floating data processing instructions to handle 256-bit floating-point vectors.

AVX includes 39 256-bit data processing instructions that are promoted from previous generations of SIMD instruction extensions, ranging from logical, blend, convert, test, unpacking, shuffling, load and stores.

AVX introduces 18 new data processing instructions that operate on 256-bit vectors. These new primitives cover the following operations:

- Non-unit-strided fetching of SIMD data. AVX provides several flexible SIMD floating-point data fetching primitives:
  - broadcast of single or multiple data elements into a 256-bit destination,
  - masked move primitives to load or store SIMD data elements conditionally,
- Intra-register manipulation of SIMD data elements. AVX provides several flexible SIMD floating-point data manipulation primitives:
  - insert/extract multiple SIMD floating-point data elements to/from 256-bit SIMD registers
  - permute primitives to facilitate efficient manipulation of floating-point data elements in 256-bit SIMD registers
- Branch handling. AVX provides several primitives to enable handling of branches in SIMD programming:

- new variable blend instructions supports four-operand syntax with non-destructive source syntax. This is more flexible than the equivalent SSE4 instruction syntax which uses the XMM0 register as the implied mask for blend selection.
- Packed TEST instructions for floating-point data.

### 1.4.3 Arithmetic Primitives for 128-bit Vector and Scalar processing

Intel AVX provides 131 128-bit numeric processing instructions that employ VEX-prefix encoding. These VEX-encoded instructions generally provide the same functionality over instructions operating on XMM register that are encoded using SIMD prefixes. The 128-bit numeric processing instructions in AVX cover floating-point and integer data processing; across 128-bit vector and scalar processing.

The enhancement in AVX on 128-bit floating-point compare operation provides 32 conditional predicates to improve programming flexibility in evaluating conditional expressions. This contrasts with floating-point SIMD compare instructions in SSE and SSE2 supporting only 8 conditional predicates.

FMA provides 60 128-bit floating-point instructions to process 128-bit vector and scalar data. The arithmetic operations cover fused multiply-add, fused multiply-subtract, signed-reversed multiply on fused multiply-add and multiply-subtract.

### 1.4.4 Non-Arithmetic Primitives for 128-bit Vector and Scalar Processing

Intel AVX provides 126 data processing instructions that employ VEX-prefix encoding. These VEX-encoded instructions generally provide the same functionality over instructions operating on XMM register that are encoded using SIMD prefixes. The 128-bit data processing instructions in AVX cover floating-point and integer data movement primitives.

Additional enhancements in AVX on 128-bit data processing primitives include 16 new instructions with the following capabilities:

- Non-unit-strided fetching of SIMD data. AVX provides several flexible SIMD floating-point data fetching primitives:
  - broadcast of single data element into a 128-bit destination,
  - masked move primitives to load or store SIMD data elements conditionally,
- Intra-register manipulation of SIMD data elements. AVX provides several flexible SIMD floating-point data manipulation primitives:
  - permute primitives to facilitate efficient manipulation of floating-point data elements in 128-bit SIMD registers
- Branch handling. AVX provides several primitives to enable handling of branches in SIMD programming:

- new variable blend instructions supports four-operand syntax with non-destructive source syntax. Branching conditions dependent on floating-point data or integer data can benefit from Intel AVX. This is more flexible than non-VEX encoded instruction syntax that uses the XMM0 register as implied mask for blend selection. While variable blend with implied XMM0 syntax is supported in SSE4 using SIMD prefix encoding, VEX-encoded 128-bit variable blend instructions only support the more flexible four-operand syntax.
- Packed TEST instructions for floating-point data.

## 1.5 GENERAL ENCRYPTION AND CRYPTOGRAPHIC PROCESSING

Intel 64 processors using 32nm processing technology introduces several primitives targeted to accelerate general-purpose block encryption and cryptographic functions using the Advanced Encryption Standard (AES) of block cipher encryption and decryption on 128-bit blocks.

General-purpose block encryption primitives are provided by PCLMULQDQ instruction, which can perform carry-less multiplication for two binary numbers up to 64-bit wide.

AES encryption involves processing 128-bit input data (plaintext) through a finite number of iterative operation, referred to as "AES round", into a 128-bit encrypted block (ciphertext). Decryption follows the reverse direction of iterative operation using the "equivalent inverse cipher" instead of the "inverse cipher".

The cryptographic processing at each round involves two input data, one is the "state", the other is the "round key". Each round uses a different "round key". The round keys are derived from the cipher key using a "key schedule" algorithm. The "key schedule" algorithm is independent of the data processing of encryption/decryption, and can be carried out independently from the encryption/decryption phase.

The AES standard supports cipher key of sizes 128, 192, and 256 bits. The respective cipher key sizes correspond to 10, 12, and 14 rounds of iteration.

The AES extensions provide two primitives to accelerate AES rounds on encryption, two primitives for AES rounds on decryption using the equivalent inverse cipher, and two instructions to support the AES key expansion procedure.

## CHAPTER 2

# APPLICATION PROGRAMMING MODEL

---

The application programming model for Intel AVX, FMA, AES and encryption primitives extend from that of Streaming SIMD Extensions (SSE) and is summarized as follows:

- The AES extensions and carry-less multiplication instruction (PCLMULQDQ) follow the same programming model as SSE, SSE2, SSE3, SSSE3, and SSE4 (see *IA-32 Intel Architecture Software Developer's Manual, Volume 1*). The detection of AES and PCLMULQDQ is described in Section 2.1.
- The AVX and FMA extensions follow a programming model analogous to that of SSE with minor differences. This is described in Section 2.1 through Section 2.8. Note however that the OS support and detection process has changed considerably.
- The numeric exception behavior of FMA is similar to previous generations of SIMD floating-point instructions. The specific details are described in Section 2.3.

CPUID instruction details for detecting AVX, FMA, AES, PCLMULQDQ are described in Section 2.9.

## 2.1 DETECTION OF PCLMULQDQ AND AES INSTRUCTIONS

Before an application attempts to use the following AES instructions: AESDEC/AESDECLAST/AESENCAESENCLAST/AESIMC/AESKEYGENASSIST, it must check that the processor supports the AES extensions. AES extensions is supported if `CPUID.01H:ECX.AES[bit 25] = 1`.

Prior to using PCLMULQDQ instruction, application must check if `CPUID.01H:ECX.PCLMULQDQ[bit 1] = 1`.

Operating systems that support handling SSE state will also support applications that use AES extensions and PCLMULQDQ instruction. This is the same requirement for SSE2, SSE3, SSSE3, and SSE4.

## 2.2 DETECTION OF AVX AND FMA INSTRUCTIONS

AVX and FMA operate on the 256-bit YMM register state. System software requirements to support YMM state is described in Chapter 3.

Application detection of new instruction extensions operating on the YMM state follows the general procedural flow in Figure 2-1.

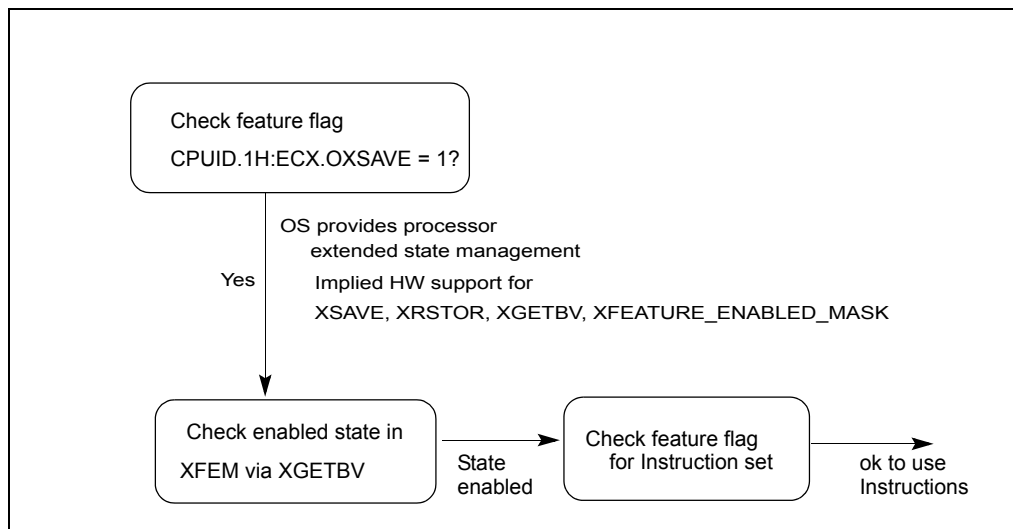

Figure 2-1. General Procedural Flow of Application Detection of AVX

Prior to using AVX, the application must identify that the operating system supports the XGETBV instruction, the YMM register state, in addition to processor's support for YMM state management using XSAVE/XRSTOR and AVX instructions. The following simplified sequence accomplishes both and is strongly recommended.

- 1) Detect CPUID.1:ECX.OSXSAVE[bit 27] = 1 (XGETBV enabled for application use<sup>1</sup>)
  - 2) Issue XGETBV and verify that XFEATURE\_ENABLED\_MASK[2:1] = '11b' (XMM state and YMM state are enabled by OS).
  - 3) detect CPUID.1:ECX.AVX[bit 28] = 1 (AVX instructions supported).
- (Step 3 can be done in any order relative to 1 and 2)

The following pseudocode illustrates this recommended application AVX detection process:

```

-----
INT supports_AVX()
{
    ; result in eax
    mov eax, 1
    cpuid
}
  
```

- 
1. If CPUID.01H:ECX.OSXSAVE reports 1, it also indirectly implies the processor supports XSAVE, XRSTOR, XGETBV, processor extended state bit vector XFEATURE\_ENABLED\_MASK register. Thus an application may streamline the checking of CPUID feature flags for XSAVE and OSXSAVE. XSETBV is a privileged instruction.

```

and ecx, 018000000H
cmp ecx, 018000000H; check both OSXSAVE and AVX feature flags
jne not_supported
; processor supports AVX instructions and XGETBV is enabled by OS
mov ecx, 0; specify 0 for XFEATURE_ENABLED_MASK register
XGETBV; result in EDX:EAX
and eax, 06H
cmp eax, 06H; check OS has enabled both XMM and YMM state support
jne not_supported
mov eax, 1
jmp done
NOT_SUPPORTED:
mov eax, 0
done:
}

```

-----

Note: It is unwise for an application to rely exclusively on CPUID.1:ECX.AVX[bit 28] or at all on CPUID.1:ECX.XSAVE[bit 26]: These indicate hardware support but not operating system support. If YMM state management is not enabled by an operating system, AVX instructions will #UD regardless of CPUID.1:ECX.AVX[bit 28]. "CPUID.1:ECX.XSAVE[bit 26] = 1" does not guarantee the OS actually uses the XSAVE process for state management.

These steps above also apply to enhanced 128-bit SIMD floating-pointing instructions in AVX (using VEX prefix-encoding) that operate on the YMM states. Application detection of VEX-encoded AES is described in Section 2.2.2.

## 2.2.1 Detection of FMA

Hardware support for FMA is indicated by CPUID.1:ECX.FMA[bit 12]=1.

Application Software must identify that hardware supports AVX as explained in Section 2.2, after that it must also detect support for FMA by CPUID.1:ECX.FMA[bit 12]. The recommended pseudocode sequence for detection of FMA is:

```

-----
INT supports_fma()
{
    ; result in eax
    mov eax, 1
    cpuid
    and ecx, 018001000H

```

```

    cmp ecx, 018001000H; check OSXSAVE, AVX, FMA feature flags
    jne not_supported
    ; processor supports AVX,FMA instructions and XGETBV is enabled by OS
    mov ecx, 0; specify 0 for XFEATURE_ENABLED_MASK register
    XGETBV; result in EDX:EAX
    and eax, 06H
    cmp eax, 06H; check OS has enabled both XMM and YMM state support
    jne not_supported
    mov eax, 1
    jmp done
NOT_SUPPORTED:
    mov eax, 0
done:
}

```

---

Note that FMA comprises of 256-bit and 128-bit SIMD instructions operating on YMM states.

## 2.2.2 Detection of VEX-Encoded AES and VPCLMULQDQ

VAESDEC/VAESDECLAST/VAESENK/VAESENCLAST/VAESIMC/VAESKEYGENASSIST instructions operate on YMM states. The detection sequence must combine checking for CPUID.1:ECX.AES[bit 25] = 1 and the sequence for detection application support for AVX.

Similarly, the detection sequence for VPCLMULQDQ must combine checking for CPUID.1:ECX.PCLMULQDQ[bit 1] = 1 and the sequence for detection application support for AVX.

This is shown in the pseudocode:

---

```

INT supports_VAES()
{
    ; result in eax
    mov eax, 1
    cpuid
    and ecx, 01A000000H
    cmp ecx, 01A000000H; check OSXSAVE, AVX and AES feature flags
    jne not_supported
}

```

; processor supports AVX and VEX.128-encoded AES instructions and XGETBV is enabled by OS

mov ecx, 0; specify 0 for XFEATURE\_ENABLED\_MASK register

XGETBV; result in EDX:EAX

and eax, 06H

cmp eax, 06H; check OS has enabled both XMM and YMM state support

jne not\_supported

mov eax, 1

jmp done

NOT\_SUPPORTED:

mov eax, 0

done:

}

INT supports\_VPCLMULQDQ()

{ ; result in eax

mov eax, 1

cpuid

and ecx, 018000002H

cmp ecx, 018000002H; check OSXSAVE, AVX and PCLMULQDQ feature flags

jne not\_supported

; processor supports AVX and VPCLMULQDQ instructions and XGETBV is enabled by OS

mov ecx, 0; specify 0 for XFEATURE\_ENABLED\_MASK register

XGETBV; result in EDX:EAX

and eax, 06H

cmp eax, 06H; check OS has enabled both XMM and YMM state support

jne not\_supported

mov eax, 1

jmp done

NOT\_SUPPORTED:

mov eax, 0

done:

}

## 2.3 FUSED-MULTIPLY-ADD (FMA) NUMERIC BEHAVIOR

FMA instructions can perform fused-multiply-add operations (including fused-multiply-subtract, and other varieties) on packed and scalar data elements in the instruction operands. FMA instruction provide separate instructions to handle different types of arithmetic operations on the three source operands.

FMA instruction syntax is defined using three source operands and the first source operand is updated based on the result of the arithmetic operations of the data elements of 128-bit or 256-bit operands, i.e. The first source operand is also the destination operand.

The arithmetic FMA operation performed in an FMA instruction takes one of several forms,  $r=(x*y)+z$ ,  $r=(x*y)-z$ ,  $r=-(x*y)+z$ , or  $r=-(x*y)-z$ . Packed FMA instructions can perform eight single-precision FMA operations or four double-precision FMA operations with 256-bit vectors.

Scalar FMA instructions only perform one arithmetic operation on the low order data element. The content of the rest of the data elements in the lower 128-bits of the destination operand is preserved. the upper 128bits of the destination operand are filled with zero.

An arithmetic FMA operation of the form,  $r=(x*y)+z$ , takes two IEEE-754-2008 single (double) precision values and multiplies them to form an infinite precision intermediate value. This intermediate value is added to a third single (double) precision value (also at infinite precision) and rounded to produce a single (double) precision result.

Table 2-2 describes the numerical behavior of the FMA operation,  $r=(x*y)+z$ ,  $r=(x*y)-z$ ,  $r=-(x*y)+z$ ,  $r=-(x*y)-z$  for various input values. The input values can be 0, finite non-zero (F in Table 2-2), infinity of either sign (INF in Table 2-2), positive infinity (+INF in Table 2-2), negative infinity (-INF in Table 2-2), or NaN (including QNaN or SNaN). If any one of the input values is a NAN, the result of FMA operation,  $r$ , may be a quietized NAN. The result can be either  $Q(x)$ ,  $Q(y)$ , or  $Q(z)$ , see Table 2-2. If  $x$  is a NaN, then:

- $Q(x) = x$  if  $x$  is QNaN or
- $Q(x) =$  the quietized NaN obtained from  $x$  if  $x$  is SNaN

The notation for output value in Table 2-2 are:

- "+INF": positive infinity, "-INF": negative infinity. When the result depends on a conditional expression, both values are listed in the result column and the condition is described in the comment column.
- QNaNIndefinite represents the QNaN which has the sign bit equal to 1, the second most significand field equal to 1, and the remaining significand field bits equal to 0.

- The summation or subtraction of 0s or identical values in FMA operation can lead to the following situations shown in Table 2-1
- If the FMA computation represents an invalid operation (e.g. when adding two INF with opposite signs)), the invalid exception is signaled, and the MXCSR.IE flag is set.

**Table 2-1. Rounding behavior of Zero Result in FMA Operation**

| $x*y$ | $z$  | $(x*y) + z$                              | $(x*y) - z$                              | $-(x*y) + z$                             | $-(x*y) - z$                             |

| 0                   | F                 | F    | z                   | -z                  | z                   | -z                  |  |

| X<br>(multiplicand) | Y<br>(multiplier) | Z | $r=(x*y)+z$ | $r=(x*y)-z$ | $r = -(x*y)+z$ | $r = -(x*y)-z$ | Comment  |
|---------------------|-------------------|---|-------------|-------------|----------------|----------------|--|
| F                   | 0                 | F | Z           | -Z          | Z              | -Z             |  |
| F                   | F                 | 0 | $x*y$       | $x*y$       | $-x*y$         | $-x*y$         | Rounded to the destination precision, with bounded exponent  |
| F                   | F                 | F | $(x*y)+z$   | $(x*y)-z$   | $-(x*y)+z$     | $-(x*y)-z$     | Rounded to the destination precision, with bounded exponent; however, if the exact values of $x*y$ and $z$ are equal in magnitude with signs resulting in the FMA operation producing 0, the rounding behavior described in Table 2-1. |

If unmasked floating-point exceptions are signaled (invalid operation, denormal operand, overflow, underflow, or inexact result) the result register is left unchanged and a floating-point exception handler is invoked.

### 2.3.1 FMA Instruction Operand Order and Arithmetic Behavior

FMA instruction mnemonics are defined explicitly with an ordered three digits, e.g. VFMADD132PD. The value of each digit refers to the ordering of the three source operand as defined by instruction encoding specification:

- '1': The first source operand (also the destination operand) in the syntactical order listed in this specification.
- '2': The second source operand in the syntactical order. This is a YMM/XMM register, encoded using VEX prefix.
- '3': The third source operand in the syntactical order. The first and third operand are encoded following ModR/M encoding rules.

The ordering of each digit within the mnemonic refers to the floating-point data listed on the right-hand side of the arithmetic equation of each FMA operation (see Table 2-2):

- The first position in the three digit ordering of a FMA mnemonic refers to the first FP data expressed in the arithmetic equation of FMA operation, the multiplicand.
- The second position in the three digit FMA mnemonic refers to the second FP data expressed in the arithmetic equation of FMA operation, the multiplier.
- The third position in the three digit FMA mnemonic refers to the FP data being added/subtracted to the multiplication result.

Note non-numerical result of an FMA operation do not resemble the mathematically-defined commutative property between the multiplicand and the multiplier values (see Table 2-2). Consequently, software tools (such as an assembler) may support a complementary set of FMA mnemonics for each FMA instruction for ease of programming to take advantage of the mathematical property of commutative multiplications. For example, an assembler may optionally support the complementary mnemonic "VFMADD312PD" in addition to the true mnemonic "VFMADD132PD". The assembler will generate the same instruction opcode sequence corresponding to VFMADD132PD. The processor executes VFMADD132PD and report any NAN conditions based on the definition of VFMADD132PD. Similarly, if the complementary mnemonic VFMADD123PD is supported by an assembler at source level, it must generate the opcode sequence corresponding to VFMADD213PD; the complementary mnemonic VFMADD321PD must produce the opcode sequence defined by VFMADD231PD. In the absence of FMA operations reporting a NAN result, the numerical results of using either mnemonic with an assembler supporting both mnemonics will match the behavior defined in Table 2-2. Support for the complementary FMA mnemonics by software tools is optional.

## 2.4 ACCESSING YMM REGISTERS

The lower 128 bits of a YMM register is aliased to the corresponding XMM register. Legacy SSE instructions (i.e. SIMD instructions operating on XMM state but not using the VEX prefix, also referred to non-VEX encoded SIMD instructions) will not access the upper bits (255:128) of the YMM registers. AVX and FMA instructions with a VEX prefix and vector length of 128-bits zeroes the upper 128 bits of the YMM register. See Chapter 2, "Programming Considerations with 128-bit SIMD Instructions" for more details.

Upper bits of YMM registers (255:128) can be read and written by many instructions with a VEX.256 prefix.

XSAVE and XRSTOR may be used to save and restore the upper bits of the YMM registers.

## 2.5 MEMORY ALIGNMENT

Memory alignment requirements on VEX-encoded instruction differs from non-VEX-encoded instructions. Memory alignment applies to non-VEX-encoded SIMD instructions in three categories:

- Explicitly-aligned SIMD load and store instructions accessing 16 bytes of memory (e.g. MOVAPD, MOVAPS, MOVDQA, etc.). These instructions always require memory address to be aligned on 16-byte boundary.
- Explicitly-unaligned SIMD load and store instructions accessing 16 bytes or less of data from memory (e.g. MOVUPD, MOVUPS, MOVDQU, MOVQ, MOVD, etc.). These instructions do not require memory address to be aligned on 16-byte boundary.
- The vast majority of arithmetic and data processing instructions in legacy SSE instructions (non-VEX-encoded SIMD instructions) support memory access semantics. When these instructions access 16 bytes of data from memory, the memory address must be aligned on 16-byte boundary.

Most arithmetic and data processing instructions encoded using the VEX prefix and performing memory accesses have more flexible memory alignment requirements than instructions that are encoded without the VEX prefix. Specifically,

- With the exception of explicitly aligned 16 or 32 byte SIMD load/store instructions, most VEX-encoded, arithmetic and data processing instructions operate in a flexible environment regarding memory address alignment, i.e. VEX-encoded instruction with 32-byte or 16-byte load semantics will support unaligned load operation by default. Memory arguments for most instructions with VEX prefix operate normally without causing #GP(0) on any byte-granularity alignment (unlike Legacy SSE instructions). The instructions that require explicit memory alignment requirements are listed in Table 2-4.

Software may see performance penalties when unaligned accesses cross cacheline boundaries, so reasonable attempts to align commonly used data sets should continue to be pursued.

Atomic memory operation in Intel 64 and IA-32 architecture is guaranteed only for a subset of memory operand sizes and alignment scenarios. The list of guaranteed atomic operations are described in Section 7.1.1 of *IA-32 Intel® Architecture Software Developer's Manual, Volumes 3A*. AVX and FMA instructions do not introduce any new guaranteed atomic memory operations.

AVX and FMA will generate an #AC(0) fault on misaligned 4 or 8-byte memory references in Ring-3 when CR0.AM=1. 16 and 32-byte memory references will not generate #AC(0) fault. See Table 2-3 for details.

Certain AVX instructions always require 16- or 32-byte alignment (see the complete list of such instructions in Table 2-4). These instructions will #GP(0) if not aligned to 16-byte boundaries (for 16-byte granularity loads and stores) or 32-byte boundaries (for 32-byte loads and stores).

**Table 2-3. Alignment Faulting Conditions when Memory Access is Not Aligned**

|                                  |                  | <b>EFLAGS.AC==1 &amp;&amp; Ring-3 &amp;&amp; CR0.AM == 1</b>           | <b>0</b> | <b>1</b> |
|----------------------------------|------------------|--|----------|----------|
| <b>Instruction Type</b>          | <b>AVX, FMA,</b> | 16- or 32-byte “explicitly unaligned” loads and stores (see Table 2-5) | no fault | no fault |
|                                  |                  | VEX op YMM, m256   | no fault | no fault |
|                                  |                  | VEX op XMM, m128   | no fault | no fault |
|                                  |                  | “explicitly aligned” loads and stores (see Table 2-4)                  | #GP(0)   | #GP(0)   |
|                                  |                  | 2, 4, or 8-byte loads and stores                                       | no fault | #AC(0)   |
|                                  | <b>SSE</b>       | 16 byte “explicitly unaligned” loads and stores (see Table 2-5)        | no fault | no fault |
|                                  |                  | op XMM, m128   | #GP(0)   | #GP(0)   |
|                                  |                  | “explicitly aligned” loads and stores (see Table 2-4)                  | #GP(0)   | #GP(0)   |
| 2, 4, or 8-byte loads and stores |                  | no fault   | #AC(0)   |          |

**Table 2-4. Instructions Requiring Explicitly Aligned Memory**

| <b>Require 16-byte alignment</b> | <b>Require 32-byte alignment</b> |

## 2.6 SIMD FLOATING-POINT EXCEPTIONS

AVX and FMA instructions can generate SIMD floating-point exceptions (#XM) and respond to exception masks in the same way as Legacy SSE instructions. When CR4.OSXMMEXCPT=0 any unmasked FP exceptions generate an Undefined Opcode exception (#UD).

AVX FP exceptions are created in a similar fashion (differing only in number of elements) to Legacy SSE and SSE2 instructions capable of generating SIMD floating-point exceptions.

AVX introduces no new arithmetic operations (AVX floating-point are analogues of existing Legacy SSE instructions). FMA introduces new arithmetic operations, detailed FMA numeric behavior are described in Section 2.3.

## 2.7 INSTRUCTION EXCEPTION SPECIFICATION

To use this reference of instruction exceptions, look at each instruction for a description of the particular exception type of interest. For example, ADDPS contains the entry:

*"See Exceptions Type 2"*

In this entry, "Type2" can be looked up in Table 2-6.

The instruction's corresponding CPUID feature flag can be identified in the fourth column of the Instruction summary table.

Note: #UD on CPUID feature flags=0 is not guaranteed in a virtualized environment if the hardware supports the feature flag.

**Table 2-6. Exception class description**

| Exception Class | Instruction set        | Mem arg                              | Floating-Point Exceptions (#XM) |
|-----------------|------------------------|--------------------------------------|---------------------------------|
| Type 1          | AVX,<br>Legacy SSE     | 16/32 byte<br>explicitly aligned     | none                            |
| Type 2          | AVX, FMA<br>Legacy SSE | 16/32 byte not<br>explicitly aligned | yes                             |
| Type 3          | AVX, FMA<br>Legacy SSE | < 16 byte                            | yes                             |
| Type 4          | AVX,<br>Legacy SSE     | 16/32 byte not<br>explicitly aligned | no                              |
| Type 5          | AVX,<br>Legacy SSE     | < 16 byte                            | no                              |
| Type 6          | AVX (no Legacy<br>SSE) | Varies                               | (At present,<br>none do)        |
| Type 7          | AVX,<br>Legacy SSE     | none                                 | none                            |
| Type 8          | AVX                    | none                                 | none                            |
| Type 11         | F16C                   | 8 or 16 byte                         | yes                             |

See Table 2-7 for lists of instructions in each exception class.

**Table 2-7. Instructions in each Exception Class**

| Exception Class | Instruction  |
|-----------------|--|
| Type 1          | (V)MOVAPD, (V)MOVAPS, (V)MOVDQA, (V)MOVNTDQ, (V)MOVNTDQA, (V)MOVNTPD, (V)MOVNTPS   |
| Type 2          | (V)ADDPD, (V)ADDPS, (V)ADDSUBPD, (V)ADDSUBPS, (V)CMPPD, (V)CMPPS, (V)CVTDQ2PS, (V)CVTPD2DQ, (V)CVTPD2PS, (V)CVTPS2DQ, (V)CVTTPD2DQ, (V)CVTTPS2DQ, (V)DIVPD, (V)DIVPS, (V)DPPD*, (V)DPPS*, VFMADD132PD, VFMADD213PD, VFMADD231PD, VFMADD132PS, VFMADD213PS, VFMADD231PS, VFMADDSUB132PD, VFMADDSUB213PD, VFMADDSUB231PD, VFMADDSUB132PS, VFMADDSUB213PS, VFMADDSUB231PS, VFMSUBADD132PD, VFMSUBADD213PD, VFMSUBADD231PD, VFMSUBADD132PS, VFMSUBADD213PS, VFMSUBADD231PS, VFMSUB132PD, VFMSUB213PD, VFMSUB231PD, VFMSUB132PS, VFMSUB213PS, VFMSUB231PS, VFNMADD132PD, VFNMADD213PD, VFNMADD231PD, VFNMADD132PS, VFNMADD213PS, VFNMADD231PS, VFNMSUB132PD, VFNMSUB213PD, VFNMSUB231PD, VFNMSUB132PS, VFNMSUB213PS, VFNMSUB231PS, (V)HADDPD, (V)HADDPDPS, (V)HSUBPD, (V)HSUBPS, (V)MAXPD, (V)MAXPS, (V)MINPD, (V)MINPS, (V)MULPD, (V)MULPS, (V)ROUNDPS, (V)ROUNDPS, (V)SQRTPD, (V)SQRTPS, (V)SUBPD, (V)SUBPS |
| Type 3          | (V)ADDS, (V)ADDS, (V)CMPSD, (V)CMPSS, (V)COMISD, (V)COMISS, (V)CVTSP2D, (V)CVTSD2SI, (V)CVTSD2SS, (V)CVTSI2SD, (V)CVTSI2SS, (V)CVTSS2SD, (V)CVTSS2SI, (V)CVTTSD2SI, (V)CVTTSS2SI, (V)DIVSD, (V)DIVSS, VFMADD132SD, VFMADD213SD, VFMADD231SD, VFMADD132SS, VFMADD213SS, VFMADD231SS, VFMSUB132SD, VFMSUB213SD, VFMSUB231SD, VFMSUB132SS, VFMSUB213SS, VFMSUB231SS, VFNMADD132SD, VFNMADD213SD, VFNMADD231SD, VFNMADD132SS, VFNMADD213SS, VFNMADD231SS, VFNMSUB132SD, VFNMSUB213SD, VFNMSUB231SD, VFNMSUB132SS, VFNMSUB213SS, VFNMSUB231SS, (V)MAXSD, (V)MAXSS, (V)MINS, (V)MINSS, (V)MULSD, (V)MULSS, (V)ROUNDSD, (V)ROUNDSS, (V)SQRTSD, (V)SQRTSS, (V)SUBSD, (V)SUBSS, (V)UCOMISD, (V)UCOMISS  |

| Exception Class | Instruction   |
|-----------------|---|
| Type 4          | (V)AESDEC, (V)AESDECLAST, (V)AESENC, (V)AESENCLAST, (V)AESIMC, (V)AESKEYGENASSIST, (V)ANDPD, (V)ANDPS, (V)ANDNPD, (V)ANDNPS, (V)BLENDPD, (V)BLENDPS, (V)BLENDVPD, (V)BLENDVPS, (V)LDDQU, (V)MASKMOVDQU, (V)PTEST, (V)TESTPS, (V)TESTPD, (V)MOVDQU*, (V)MOVSHDUP, (V)MOVSLDUP, (V)MOVUPD*, (V)MOVUPS*, (V)MPSADBW, (V)ORPD, (V)ORPS, (V)PABSB, (V)PABSW, (V)PABSD, (V)PACKSSWB, (V)PACKSSDW, (V)PACKUSWB, (V)PACKUSDW, (V)PADDB, (V)PADDW, (V)PADDD, (V)PADDQ, (V)PADDSB, (V)PADDSW, (V)PADDUSB, (V)PADDUSW, (V)PALIGNR, (V)PAND, (V)PANDN, (V)PAVGB, (V)PAVGW, (V)PBLENDVB, (V)PBLENDW, (V)PCMP(E/I)STRI/M, (V)PCMPEQB, (V)PCMPEQW, (V)PCMPEQD, (V)PCMPEQQ, (V)PCMPGTB, (V)PCMPGTW, (V)PCMPGTD, (V)PCMPGTQ, (V)PCLMULQDQ, (V)PHADDW, (V)PHADD, (V)PHADDSW, (V)PHMINPOSUW, (V)PHSUBD, (V)PHSUBW, (V)PHSUBSW, |
|                 | (V)PMADDWD, (V)PMADDUBSW, (V)PMAWSB, (V)PMAWSW, (V)PMAWSD, (V)PMAWUB, (V)PMAWUW, (V)PMAWUD, (V)PMINSB, (V)PMINSW, (V)PMINSD, (V)PMINUB, (V)PMINUW, (V)PMINUD, (V)PMULHUW, (V)PMULHRW, (V)PMULHW, (V)PMULLW, (V)PMULLD, (V)PMULUDQ, (V)PMULDQ, (V)POR, (V)PSADBW, (V)PSHUFB, (V)PSHUF, (V)PSHUFHW, (V)PSHUFLW, (V)PSIGNB, (V)PSIGNW, (V)PSIGND, (V)PSLLW, (V)PSLLD, (V)PSLLQ, (V)PSRAW, (V)PSRAD, (V)PSRLW, (V)PSRLD, (V)PSRLQ, (V)PSUBB, (V)PSUBW, (V)PSUBD, (V)PSUBQ, (V)PSUBSB, (V)PSUBSW, (V)PUNPCKHWD, (V)PUNPCKHWDQ, (V)PUNPCKHWDQDQ, (V)PUNPCKLWD, (V)PUNPCKLWDQ, (V)PUNPCKLWDQDQ, (V)PXOR, (V)RCPPS, (V)RSQRTPS, (V)SHUFPD, (V)SHUFPS, (V)UNPCKHPD, (V)UNPCKHPS, (V)UNPCKLPD, (V)UNPCKLPS, (V)XORPD, (V)XORPS  |
| Type 5          | (V)CVTQDQ2PD, (V)EXTRACTPS, (V)INSERTPS, (V)MOVD, (V)MOVQ, (V)MOVDDUP, (V)MOVLPD, (V)MOVLPS, (V)MOVHPD, (V)MOVHPS, (V)MOVSD, (V)MOVSS, (V)PEXTRB, (V)PEXTRD, (V)PEXTRW, (V)PEXTRQ, (V)PINSRB, (V)PINSRD, (V)PINSRW, (V)PINSRQ, (V)RCPPS, (V)RSQRTSS, (V)PMOVSX/ZX, (V)VLDMXCSR*, (V)VSTMXCSR  |
| Type 6          | VEXTRACTF128, VPERMILPD, VPERMILPS, VPERM2F128, VBROADCASTSS, VBROADCASTSD, VBROADCASTF128, VINSERTF128, VMASKMOVPS**, VMASKMOVPD**   |
| Type 7          | (V)MOVLHPS, (V)MOVHLP, (V)MOVMSKPD, (V)MOVMSKPS, (V)PMOVMASKB, (V)PSLLDQ, (V)PSRLDQ, (V)PSLLW, (V)PSLLD, (V)PSLLQ, (V)PSRAW, (V)PSRAD, (V)PSRLW, (V)PSRLD, (V)PSRLQ   |
| Type 8          | VZEROALL, VZERoupper  |
| Type 11         | VCVTPH2PS, VCVTSP2PH  |

(\*) - Additional exception restrictions are present - see the Instruction description for details

(\*\*) - Instruction behavior on alignment check reporting with mask bits of less than all 1s are the same as with mask bits of all 1s, i.e. no alignment checks are performed.

Table 2-7 classifies exception behaviors for AVX instructions. Within each class of exception conditions that are listed in Table 2-10 through Table 2-16, certain subsets of AVX instructions may be subject to #UD exception depending on the encoded value of the VEX.L field. Table 2-9 provides supplemental information of AVX instructions that may be subject to #UD exception if encoded with incorrect values in the VEX.W or VEX.L field.

**Table 2-8. #UD Exception and VEX.W=1 Encoding**

| Exception Class | #UD If VEX.W = 1 in all modes   | #UD If VEX.W = 1 in non-64-bit modes |
|-----------------|---|--------------------------------------|
| Type 1          |   |                                      |
| Type 2          |   |                                      |

## 2.7.6 Exceptions Type 6 (VEX-Encoded Instructions Without Legacy SSE Analogues)

Note: At present, the AVX instructions in this category do not generate floating-point exceptions.

**Table 2-15. Type 6 Class Exception Conditions**

| Exception                  | Real | Virtual 80x86 | Protected and Compatibility | 64-bit | Cause of Exception   |
|----------------------------|------|---------------|-----------------------------|--------|--|
| Invalid Opcode, #UD        | X    | X             |                             |        | VEX prefix   |
|                            |      |               | X                           | X      | If XFEATURE_ENABLED_MASK[2:1] != '11b'.<br>If CR4.OSXSAVE[bit 18]=0.   |
|                            |      |               | X                           | X      | If preceded by a LOCK prefix (FOH)   |
|                            |      |               | X                           | X      | If any REX, F2, F3, or 66 prefixes precede a VEX prefix  |
|                            |      |               | X                           | X      | If any corresponding CPUID feature flag is '0'   |
| Device Not Available, #NM  |      |               | X                           | X      | If CR0.TS[bit 3]=1   |
| Stack, SS(0)               |      |               | X                           |        | For an illegal address in the SS segment   |
|                            |      |               |                             | X      | If a memory address referencing the SS segment is in a non-canonical form  |
| General Protection, #GP(0) |      |               | X                           |        | For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.  |
|                            |      |               |                             | X      | If the memory address is in a non-canonical form.  |
| Page Fault #PF(fault-code) |      |               | X                           | X      | For a page fault   |
| Alignment Check #AC(0)     |      |               | X                           | X      | For 4 or 8 byte memory references if alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3. |

## 2.7.7 Exceptions Type 7 (No FP exceptions, no memory arg)

Table 2-16. Type 7 Class Exception Conditions

| Exception                 | Real | Virtual 80x86 | Protected and Compatibility | 64-bit | Cause of Exception  |
|---------------------------|------|---------------|-----------------------------|--------|---|
| Invalid Opcode, #UD       | X    | X             |                             |        | VEX prefix  |
|                           |      |               | X                           | X      | VEX prefix:<br>If XFEATURE_ENABLED_MASK[2:1] != '11b'.<br>If CR4.OSXSAVE[bit 18]=0. |
|                           | X    | X             | X                           | X      | Legacy SSE instruction:<br>If CR0.EM[bit 2] = 1.<br>If CR4.OSFXSR[bit 9] = 0.       |
|                           | X    | X             | X                           | X      | If preceded by a LOCK prefix (F0H)  |
|                           |      |               | X                           | X      | If any REX, F2, F3, or 66 prefixes precede a VEX prefix                             |
|                           | X    | X             | X                           | X      | If any corresponding CPUID feature flag is '0'                                      |
| Device Not Available, #NM |      |               | X                           | X      | If CR0.TS[bit 3]=1  |

## 2.7.8 Exceptions Type 8 (AVX and no memory argument)

**Table 2-17. Type 8 Class Exception Conditions**

| Exception                 | Real | Virtual 80x86 | Protected and Compatibility | 64-bit | Cause of Exception   |
|---------------------------|------|---------------|-----------------------------|--------|--|
| Invalid Opcode, #UD       | X    | X             |                             |        | Always in Real or Virtual 80x86 mode   |
|                           |      |               | X                           | X      | If XFEATURE_ENABLED_MASK[2:1] != '11b'.<br>If CR4.OSXSAVE[bit 18]=0.<br>If CPUID.01H.ECX.AVX[bit 28]=0.<br>If VEX.vvvv != 1111B. |
|                           | X    | X             | X                           | X      | If proceeded by a LOCK prefix (F0H)  |
| Device Not Available, #NM |      |               | X                           | X      | If CR0.TS[bit 3]=1.  |

## 2.7.9 Exception Type 11 (VEX-only, mem arg no AC, floating-point exceptions)

**Table 2-18. Type 11 Class Exception Conditions**

| Exception                          | Real | Virtual 80x86 | Protected and Compatibility | 64-bit | Cause of Exception  |
|------------------------------------|------|---------------|-----------------------------|--------|---|
| Invalid Opcode, #UD                | X    | X             |                             |        | VEX prefix  |
|                                    |      |               | X                           | X      | VEX prefix:<br>If XFEATURE_ENABLED_MASK[2:1] != '11b'.<br>If CR4.OSXSAVE[bit 18]=0.   |
|                                    | X    | X             | X                           | X      | If preceded by a LOCK prefix (FOH)  |
|                                    |      |               | X                           | X      | If any REX, F2, F3, or 66 prefixes precede a VEX prefix                               |
|                                    | X    | X             | X                           | X      | If any corresponding CPUID feature flag is '0'  |
| Device Not Available, #NM          | X    | X             | X                           | X      | If CR0.TS[bit 3]=1  |
| Stack, SS(0)                       |      |               | X                           |        | For an illegal address in the SS segment  |
|                                    |      |               |                             | X      | If a memory address referencing the SS segment is in a non-canonical form             |
| General Protection, #GP(0)         |      |               | X                           |        | For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments. |
|                                    |      |               |                             | X      | If the memory address is in a non-canonical form.                                     |
|                                    | X    | X             |                             |        | If any part of the operand lies outside the effective address space from 0 to FFFFH   |
| Page Fault #PF(fault-code)         |      | X             | X                           | X      | For a page fault  |
| SIMD Floating-point Exception, #XM | X    | X             | X                           | X      | If an unmasked SIMD floating-point exception and CR4.OSXMMEXCPT[bit 10] = 1           |

## 2.8 PROGRAMMING CONSIDERATIONS WITH 128-BIT SIMD INSTRUCTIONS

VEX-encoded SIMD instructions generally operate on the 256-bit YMM register state. In contrast, non-VEX encoded instructions (e.g from SSE to AES) operating on XMM registers only access the lower 128-bit of YMM registers. Processors supporting both

256-bit VEX-encoded instruction and legacy 128-bit SIMD instructions has internal state to manage the upper and lower halves of the YMM states. Functionally, VEX-encoded SIMD instructions can be intermixed with legacy SSE instructions (non-VEX-encoded SIMD instructions operating on XMM registers). However, there is a performance impact with intermixing VEX-encoded SIMD instructions (AVX, FMA) and Legacy SSE instructions that only operate on the XMM register state.

The general programming considerations to realize optimal performance are the following:

- Minimize transition delays and partial register stalls with YMM registers accesses: Intermixed 256-bit, 128-bit or scalar SIMD instructions that are encoded with VEX prefixes have no transition delay due to internal state management. Sequences of legacy SSE instructions (including SSE2, and subsequent generations non-VEX-encoded SIMD extensions) that are not intermixed with VEX-encoded SIMD instructions are not subject to transition delays.
- When an application must employ AVX and/or FMA, along with legacy SSE code, it should minimize the number of transitions between VEX-encoded instructions and legacy, non-VEX-encoded SSE code. Section 2.8.1 provides recommendation for software to minimize the impact of transitions between VEX-encoded code and legacy SSE code.

In addition to performance considerations, programmers should also be cognizant of the implications of VEX-encoded AVX instructions with the expectations of system software components that manage the processor state components enabled by XCR0. For additional information see Section 4.1.9.1, "Vector Length Transition and Programming Considerations".

## 2.8.1 Clearing Upper YMM State Between AVX and Legacy SSE Instructions

There is no transition penalty if an application clears the upper bits of all YMM registers (set to '0') via `VZERoupper`, `VZEROALL`, before transitioning between AVX instructions and legacy SSE instructions. Note: clearing the upper state via sequences of `XORPS` or loading '0' values individually may be useful for breaking dependency, but will not avoid state transition penalties.

Example 1: an application using 256-bit AVX instructions makes calls to a library written using Legacy SSE instructions. This would encounter a delay upon executing the first Legacy SSE instruction in that library and then (after exiting the library) upon executing the first AVX instruction. To eliminate both of these delays, the user should execute the instruction `VZERoupper` prior to entering the legacy library and (after exiting the library) before executing in a 256-bit AVX code path.

Example 2: a library using 256-bit AVX instructions is intended to support other applications that uses legacy SSE instructions. Such a library function should execute

VZEROUPPER prior to executing other VEX-encoded instructions. The library function should issue VZEROUPPER at the end of the function before it returns to the calling application. This will prevent the calling application to experience delay when it starts to execute legacy SSE code.

### 2.8.2 Using AVX 128-bit Instructions Instead of Legacy SSE instructions

Applications using AVX and FMA should migrate legacy 128-bit SIMD instructions to their 128-bit AVX equivalents. AVX supplies the full complement of 128-bit SIMD instructions except for AES and PCLMULQDQ.

### 2.8.3 Unaligned Memory Access and Buffer Size Management

The majority of AVX instructions support loading 16/32 bytes from memory without alignment restrictions (A number non-VEX-encoded SIMD instructions also don't require 16-byte address alignment, e.g. MOVDQU, MOVUPS, MOVUPD, LDDQU, PCMPSTRI/PCMPSTRM/PCMPISTRI/PCMPISTRM). A buffer size management issue related to unaligned SIMD memory access is discussed here.

The size requirements for memory buffer allocation should consider unaligned SIMD memory semantics and application usage. Frequently a caller function may pass an address pointer in conjunction with a length parameter. From the caller perspective, the length parameter usually corresponds to the limit of the allocated memory buffer range, or it may correspond to certain application-specific configuration parameter that have indirect relationship with valid buffer size.

For certain types of application usage, it may be desirable to make distinctions between valid buffer range limit versus other application specific parameters related memory access patterns, examples of the latter may be stride distance, frame dimensions, etc. There may be situations that a callee wishes to load 16-bytes of data with parts of the 16-bytes lying outside the valid memory buffer region to take advantage of the efficiency of SIMD load bandwidth and discard invalid data elements outside the buffer boundary. An example of this may be in video processing of frames having dimensions that are not modular 16 bytes.

To support the added margin of safety in situations of buffer size allocation and iterative pointer advancement occurring across modules of different software visibility. The standard programming practice of caller function allocation of buffer size based on non-SIMD processing requirement should consider an added padding size to support newer SIMD extensions offering more lax alignment restrictions. The extra padding space can prevent the rare occurrence of access rights violation described below:

- A present page in the linear address space being used by ring 3 code is followed by a page owned by ring 0 code,
- A caller routine allocates a memory buffer without adding extra pad space and passes the buffer address to a callee routine,

- A callee routine implements an iterative processing algorithm by advancing an address pointer relative to the buffer address using SIMD instructions with unaligned 16/32 load semantics
- The callee routine may choose to load 16/32 bytes near buffer boundary with the intent to discard invalid data outside the data buffer allocated by the caller.
- If the valid data buffer extends to the end of the present page, unaligned 16/32 byte loads near the end of a present page may spill over to the subsequent ring-0 page and causing a #GP.

As a general rule, the minimal padding size should be the width the SIMD register that might be used in conjunction with unaligned SIMD memory access.

## 2.9 CPUID INSTRUCTION

### CPUID—CPU Identification

| Opcode | Instruction | 64-Bit Mode | Compat/<br>Leg Mode | Description   |
|--------|-------------|-------------|---------------------|---|
| OF A2  | CPUID       | Valid       | Valid               | Returns processor identification and feature information to the EAX, EBX, ECX, and EDX registers, as determined by input entered in EAX (in some cases, ECX as well). |

#### Description

The ID flag (bit 21) in the EFLAGS register indicates support for the CPUID instruction. If a software procedure can set and clear this flag, the processor executing the procedure supports the CPUID instruction. This instruction operates the same in non-64-bit modes and 64-bit mode.

CPUID returns processor identification and feature information in the EAX, EBX, ECX, and EDX registers.<sup>1</sup> The instruction's output is dependent on the contents of the EAX register upon execution (in some cases, ECX as well). For example, the following pseudocode loads EAX with 00H and causes CPUID to return a Maximum Return Value and the Vendor Identification String in the appropriate registers:

```
MOV EAX, 00H
CPUID
```

---

1. On Intel 64 processors, CPUID clears the high 32 bits of the RAX/RBX/RCX/RDX registers in all modes.

Table 2-19 shows information returned, depending on the initial value loaded into the EAX register. Table 2-20 shows the maximum CPUID input value recognized for each family of IA-32 processors on which CPUID is implemented.

Two types of information are returned: basic and extended function information. If a value is entered for CPUID.EAX is invalid for a particular processor, the data for the highest basic information leaf is returned. For example, using the Intel Core 2 Duo E6850 processor, the following is true:

- CPUID.EAX = 05H (\* Returns MONITOR/MWAIT leaf. \*)
- CPUID.EAX = 0AH (\* Returns Architectural Performance Monitoring leaf. \*)
- CPUID.EAX = 0BH (\* INVALID: Returns the same information as CPUID.EAX = 0AH. \*)
- CPUID.EAX = 80000008H (\* Returns virtual/physical address size data. \*)
- CPUID.EAX = 8000000AH (\* INVALID: Returns same information as CPUID.EAX = 0AH. \*)

When CPUID returns the highest basic leaf information as a result of an invalid input EAX value, any dependence on input ECX value in the basic leaf is honored.

CPUID can be executed at any privilege level to serialize instruction execution. Serializing instruction execution guarantees that any modifications to flags, registers, and memory for previous instructions are completed before the next instruction is fetched and executed.

### INPUT EAX = 0: Returns CPUID's Highest Value for Basic Processor Information and the Vendor Identification String

When CPUID executes with EAX set to 0, the processor returns the highest value the CPUID recognizes for returning basic processor information. The value is returned in the EAX register (see Table 2-20) and is processor specific.

A vendor identification string is also returned in EBX, EDX, and ECX. For Intel processors, the string is "GenuineIntel" and is expressed:

EBX ← 756e6547h (\* "Genu", with G in the low 4 bits of BL \*)

EDX ← 49656e69h (\* "inel", with i in the low 4 bits of DL \*)

ECX ← 6c65746eh (\* "ntel", with n in the low 4 bits of CL \*)

### INPUT EAX = 8000000H: Returns CPUID's Highest Value for Extended Processor Information

When CPUID executes with EAX set to 0, the processor returns the highest value the processor recognizes for returning extended processor information. The value is returned in the EAX register (see Table 2-20) and is processor specific.

**Table 2-20. Highest CPUID Source Operand for Intel 64 and IA-32 Processors**

| Intel 64 or IA-32 Processors                                      | Highest Value in EAX  |                               |
|---|-----------------------|-------------------------------|
|   | Basic Information     | Extended Function Information |
| Earlier Intel486 Processors                                       | CPUID Not Implemented | CPUID Not Implemented         |
| Later Intel486 Processors and Pentium Processors                  | 01H                   | Not Implemented               |
| Pentium Pro and Pentium II Processors, Intel® Celeron® Processors | 02H                   | Not Implemented               |
| Pentium III Processors  | 03H                   | Not Implemented               |
| Pentium 4 Processors  | 02H                   | 80000004H                     |
| Intel Xeon Processors   | 02H                   | 80000004H                     |
| Pentium M Processor   | 02H                   | 80000004H                     |
| Pentium 4 Processor supporting Hyper-Threading Technology         | 05H                   | 80000008H                     |
| Pentium D Processor (8xx)   | 05H                   | 80000008H                     |
| Pentium D Processor (9xx)   | 06H                   | 80000008H                     |
| Intel Core Duo Processor  | 0AH                   | 80000008H                     |

**Table 2-20. Highest CPUID Source Operand for Intel 64 and IA-32 Processors**

| Intel 64 or IA-32 Processors                             | Highest Value in EAX |                               |
|--|----------------------|-------------------------------|
|  | Basic Information    | Extended Function Information |
| Intel Core 2 Duo Processor                               | 0AH                  | 80000008H                     |
| Intel Xeon Processor 3000, 5100, 5300 Series             | 0AH                  | 80000008H                     |
| Intel Xeon Processor 3000, 5100, 5200, 5300, 5400 Series | 0AH                  | 80000008H                     |
| Intel Core 2 Duo Processor 8000 Series                   | 0DH                  | 80000008H                     |
| Intel Xeon Processor 5200, 5400 Series                   | 0AH                  | 80000008H                     |

### IA32\_BIOS\_SIGN\_ID Returns Microcode Update Signature

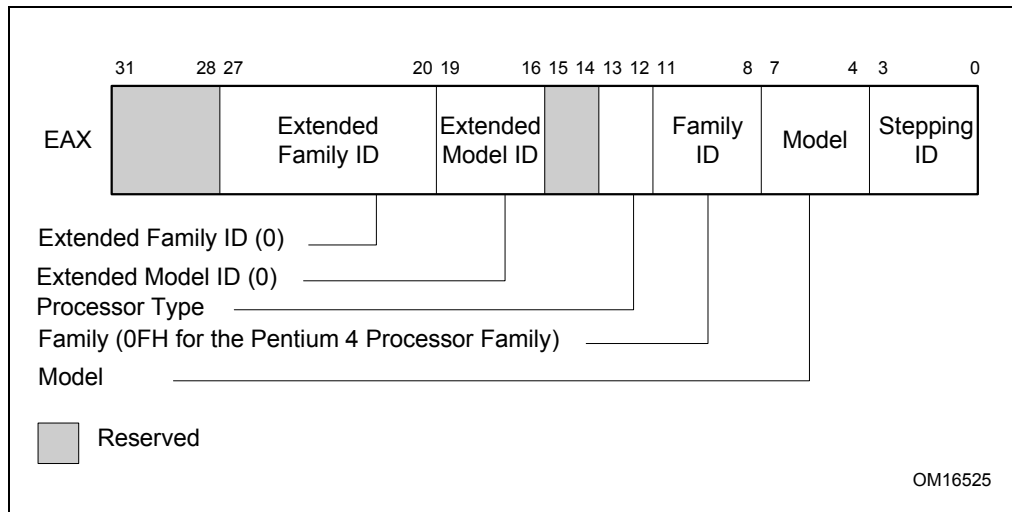

For processors that support the microcode update facility, the IA32\_BIOS\_SIGN\_ID MSR is loaded with the update signature whenever CPUID executes. The signature is returned in the upper DWORD. For details, see Chapter 10 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

### INPUT EAX = 1: Returns Model, Family, Stepping Information

When CPUID executes with EAX set to 1, version information is returned in EAX (see Figure 2-2). For example: model, family, and processor type for the Intel Xeon processor 5100 series is as follows:

- Model — 1111B
- Family — 0101B
- Processor Type — 00B

See Table 2-21 for available processor type values. Stepping IDs are provided as needed.

**Figure 2-2. Version Information Returned by CPUID in EAX**

**Table 2-21. Processor Type Field**

| Type   | Encoding |
|--|----------|
| Original OEM Processor                                 | 00B      |
| Intel OverDrive <sup>®</sup> Processor                 | 01B      |
| Dual processor (not applicable to Intel486 processors) | 10B      |
| Intel reserved   | 11B      |

**NOTE**

See "Caching Translation Information" in Chapter 4, "Paging," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*, and Chapter 14 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, for information on identifying earlier IA-32 processors.

The Extended Family ID needs to be examined only when the Family ID is 0FH. Integrate the fields into a display using the following rule:

```
IF Family_ID ≠ 0FH
  THEN Displayed_Family = Family_ID;
  ELSE Displayed_Family = Extended_Family_ID + Family_ID;
  (* Right justify and zero-extend 4-bit field. *)
```

```
FI;
(* Show Display_Family as HEX field. *)
```

The Extended Model ID needs to be examined only when the Family ID is 06H or 0FH. Integrate the field into a display using the following rule:

```
IF (Family_ID = 06H or Family_ID = 0FH)
    THEN Displayed_Model = (Extended_Model_ID << 4) + Model_ID;
    (* Right justify and zero-extend 4-bit field; display Model_ID as HEX field.*)
    ELSE Displayed_Model = Model_ID;
FI;
(* Show Display_Model as HEX field. *)
```

### INPUT EAX = 1: Returns Additional Information in EBX

When CPUID executes with EAX set to 1, additional information is returned to the EBX register:

- Brand index (low byte of EBX) — this number provides an entry into a brand string table that contains brand strings for IA-32 processors. More information about this field is provided later in this section.
- CLFLUSH instruction cache line size (second byte of EBX) — this number indicates the size of the cache line flushed with CLFLUSH instruction in 8-byte increments. This field was introduced in the Pentium 4 processor.
- Local APIC ID (high byte of EBX) — this number is the 8-bit ID that is assigned to the local APIC on the processor during power up. This field was introduced in the Pentium 4 processor.

### INPUT EAX = 1: Returns Feature Information in ECX and EDX

When CPUID executes with EAX set to 1, feature information is returned in ECX and EDX.

- Figure 2-3 and Table 2-22 show encodings for ECX.
- Figure 2-4 and Table 2-23 show encodings for EDX.

For all feature flags, a 1 indicates that the feature is supported. Use Intel to properly interpret feature flags.

### NOTE

Software must confirm that a processor feature is present using feature flags returned by CPUID prior to using the feature. Software should not depend on future offerings retaining all features.

Figure 2-3. Feature Information Returned in the ECX Register

Table 2-22. Feature Information Returned in the ECX Register

| Bit # | Mnemonic  | Description   |
|-------|-----------|---|
| 0     | SSE3      | <b>Streaming SIMD Extensions 3 (SSE3).</b> A value of 1 indicates the processor supports this technology. |
| 1     | PCLMULQDQ | A value of 1 indicates the processor supports PCLMULQDQ instruction.                                      |
| 2     | DTES64    | <b>64-bit DS Area.</b> A value of 1 indicates the processor supports DS area using 64-bit layout.         |
| 3     | MONITOR   | <b>MONITOR/MWAIT.</b> A value of 1 indicates the processor supports this feature.                         |

**Table 2-22. Feature Information Returned in the ECX Register (Continued)**

| Bit # | Mnemonic            | Description  |
|-------|---------------------|--|
| 4     | DS-CPL              | <b>CPL Qualified Debug Store.</b> A value of 1 indicates the processor supports the extensions to the Debug Store feature to allow for branch message storage qualified by CPL.  |
| 5     | VMX                 | Virtual Machine Extensions. A value of 1 indicates that the processor supports this technology.  |
| 6     | SMX                 | Safer Mode Extensions. A value of 1 indicates that the processor supports this technology. See Chapter 6, "Safer Mode Extensions Reference".   |
| 7     | EST                 | <b>Enhanced Intel SpeedStep® technology.</b> A value of 1 indicates that the processor supports this technology.   |
| 8     | TM2                 | <b>Thermal Monitor 2.</b> A value of 1 indicates whether the processor supports this technology.   |
| 9     | SSSE3               | A value of 1 indicates the presence of the Supplemental Streaming SIMD Extensions 3 (SSSE3). A value of 0 indicates the instruction extensions are not present in the processor.   |
| 10    | CNXT-ID             | <b>L1 Context ID.</b> A value of 1 indicates the L1 data cache mode can be set to either adaptive mode or shared mode. A value of 0 indicates this feature is not supported. See definition of the IA32_MISC_ENABLE MSR Bit 24 (L1 Data Cache Context Mode) for details. |
| 11    | Reserved            | Reserved   |
| 12    | FMA                 | A value of 1 indicates the processor supports FMA extensions using YMM state.  |
| 13    | CMPXCHG16B          | <b>CMPXCHG16B Available.</b> A value of 1 indicates that the feature is available.   |
| 14    | xTPR Update Control | <b>xTPR Update Control.</b> A value of 1 indicates that the processor supports changing IA32_MISC_ENABLE[bit 23].  |
| 15    | PDCM                | <b>Perfmon and Debug Capability:</b> A value of 1 indicates the processor supports the performance and debug feature indication MSR IA32_PERF_CAPABILITIES.  |
| 16    | Reserved            | Reserved   |
| 17    | PCID                | <b>Process-context identifiers.</b> A value of 1 indicates that the processor supports PCIDs and that software may set CR4.PCIDE to 1.   |
| 18    | DCA                 | A value of 1 indicates the processor supports the ability to prefetch data from a memory mapped device.  |
| 19    | SSE4.1              | A value of 1 indicates that the processor supports SSE4.1.   |
| 20    | SSE4.2              | A value of 1 indicates that the processor supports SSE4.2.   |
| 21    | x2APIC              | A value of 1 indicates that the processor supports x2APIC feature.   |

**Table 2-22. Feature Information Returned in the ECX Register (Continued)**

| Bit # | Mnemonic | Description  |
|-------|----------|--|
| 22    | MOVBE    | A value of 1 indicates that the processor supports MOVBE instruction.  |
| 23    | POPCNT   | A value of 1 indicates that the processor supports the POPCNT instruction.   |
| 24    | Reserved | Reserved   |
| 25    | AES      | A value of 1 indicates that the processor supports the AES instruction.  |
| 26    | XSAVE    | A value of 1 indicates that the processor supports the XFEATURE_ENABLED_MASK register and XSAVE/XRSTOR/XSETBV/XGETBV instructions to manage processor extended states. |
| 27    | OSXSAVE  | A value of 1 indicates that the OS has enabled support for using XGETBV/XSETBV instructions to query processor extended states.  |
| 28    | AVX      | A value of 1 indicates that processor supports AVX instructions operating on 256-bit YMM state, and three-operand encoding of 256-bit and 128-bit SIMD instructions.   |
| 29    | F16C     | A value of 1 indicates that processor supports 16-bit floating-point conversion instructions.  |
| 30    | RDRAND   | A value of 1 indicates that processor supports RDRAND instruction.   |
| 31    | Not Used | Always return 0  |

Figure 2-4. Feature Information Returned in the EDX Register

**Table 2-23. More on Feature Information Returned in the EDX Register**

| Bit # | Mnemonic | Description  |
|-------|----------|--|
| 0     | FPU      | <b>floating-point Unit On-Chip.</b> The processor contains an x87 FPU.   |
| 1     | VME      | <b>Virtual 8086 Mode Enhancements.</b> Virtual 8086 mode enhancements, including CR4.VME for controlling the feature, CR4.PVI for protected mode virtual interrupts, software interrupt indirection, expansion of the TSS with the software indirection bitmap, and EFLAGS.VIF and EFLAGS.VIP flags.   |
| 2     | DE       | <b>Debugging Extensions.</b> Support for I/O breakpoints, including CR4.DE for controlling the feature, and optional trapping of accesses to DR4 and DR5.  |
| 3     | PSE      | <b>Page Size Extension.</b> Large pages of size 4 MByte are supported, including CR4.PSE for controlling the feature, the defined dirty bit in PDE (Page Directory Entries), optional reserved bit trapping in CR3, PDEs, and PTEs.  |
| 4     | TSC      | <b>Time Stamp Counter.</b> The RDTSC instruction is supported, including CR4.TSD for controlling privilege.  |
| 5     | MSR      | <b>Model Specific Registers RDMSR and WRMSR Instructions.</b> The RDMSR and WRMSR instructions are supported. Some of the MSRs are implementation dependent.   |
| 6     | PAE      | <b>Physical Address Extension.</b> Physical addresses greater than 32 bits are supported: extended page table entry formats, an extra level in the page translation tables is defined, 2-MByte pages are supported instead of 4 Mbyte pages if PAE bit is 1. The actual number of address bits beyond 32 is not defined, and is implementation specific.   |
| 7     | MCE      | <b>Machine Check Exception.</b> Exception 18 is defined for Machine Checks, including CR4.MCE for controlling the feature. This feature does not define the model-specific implementations of machine-check error logging, reporting, and processor shutdowns. Machine Check exception handlers may have to depend on processor version to do model specific processing of the exception, or test for the presence of the Machine Check feature. |
| 8     | CX8      | <b>CMPXCHG8B Instruction.</b> The compare-and-exchange 8 bytes (64 bits) instruction is supported (implicitly locked and atomic).  |
| 9     | APIC     | <b>APIC On-Chip.</b> The processor contains an Advanced Programmable Interrupt Controller (APIC), responding to memory mapped commands in the physical address range FFFE0000H to FFFE0FFFH (by default - some processors permit the APIC to be relocated).  |
| 10    | Reserved | Reserved   |
| 11    | SEP      | <b>SYSENTER and SYSEXIT Instructions.</b> The SYSENTER and SYSEXIT and associated MSRs are supported.  |
| 12    | MTRR     | <b>Memory Type Range Registers.</b> MTRRs are supported. The MTRRcap MSR contains feature bits that describe what memory types are supported, how many variable MTRRs are supported, and whether fixed MTRRs are supported.  |

**Table 2-23. More on Feature Information Returned in the EDX Register(Continued)**

| Bit # | Mnemonic | Description  |
|-------|----------|--|
| 13    | PGE      | <b>PTE Global Bit.</b> The global bit in page directory entries (PDEs) and page table entries (PTEs) is supported, indicating TLB entries that are common to different processes and need not be flushed. The CR4.PGE bit controls this feature.   |
| 14    | MCA      | <b>Machine Check Architecture.</b> The Machine Check Architecture, which provides a compatible mechanism for error reporting in P6 family, Pentium 4, Intel Xeon processors, and future processors, is supported. The MCG_CAP MSR contains feature bits describing how many banks of error reporting MSRs are supported.   |
| 15    | CMOV     | <b>Conditional Move Instructions.</b> The conditional move instruction CMOV is supported. In addition, if x87 FPU is present as indicated by the CPUID.FPU feature bit, then the FCOMI and FCMOV instructions are supported  |
| 16    | PAT      | <b>Page Attribute Table.</b> Page Attribute Table is supported. This feature augments the Memory Type Range Registers (MTRRs), allowing an operating system to specify attributes of memory on a 4K granularity through a linear address.  |
| 17    | PSE-36   | <b>36-Bit Page Size Extension.</b> Extended 4-MByte pages that are capable of addressing physical memory beyond 4 GBytes are supported. This feature indicates that the upper four bits of the physical address of the 4-MByte page is encoded by bits 13-16 of the page directory entry.  |
| 18    | PSN      | <b>Processor Serial Number.</b> The processor supports the 96-bit processor identification number feature and the feature is enabled.  |
| 19    | CLFSH    | <b>CLFLUSH Instruction.</b> CLFLUSH Instruction is supported.  |
| 20    | Reserved | Reserved   |
| 21    | DS       | <b>Debug Store.</b> The processor supports the ability to write debug information into a memory resident buffer. This feature is used by the branch trace store (BTS) and precise event-based sampling (PEBS) facilities (see Chapter 16, “Debugging, Branch Profiles and Time-Stamp Counter,” in the <i>Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A</i> ). |
| 22    | ACPI     | <b>Thermal Monitor and Software Controlled Clock Facilities.</b> The processor implements internal MSRs that allow processor temperature to be monitored and processor performance to be modulated in predefined duty cycles under software control.   |
| 23    | MMX      | <b>Intel MMX Technology.</b> The processor supports the Intel MMX technology.  |
| 24    | FXSR     | <b>FXSAVE and FXRSTOR Instructions.</b> The FXSAVE and FXRSTOR instructions are supported for fast save and restore of the floating-point context. Presence of this bit also indicates that CR4.OSFXSR is available for an operating system to indicate that it supports the FXSAVE and FXRSTOR instructions.  |

**Table 2-23. More on Feature Information Returned in the EDX Register(Continued)**

| Bit # | Mnemonic | Description   |
|-------|----------|---|
| 25    | SSE      | <b>SSE.</b> The processor supports the SSE extensions.  |
| 26    | SSE2     | <b>SSE2.</b> The processor supports the SSE2 extensions.  |
| 27    | SS       | <b>Self Snoop.</b> The processor supports the management of conflicting memory types by performing a snoop of its own cache structure for transactions issued to the bus.   |
| 28    | HTT      | <b>Multi-Threading.</b> The physical processor package is capable of supporting more than one logical processor.  |
| 29    | TM       | <b>Thermal Monitor.</b> The processor implements the thermal monitor automatic thermal control circuitry (TCC).   |
| 30    | Reserved | Reserved  |
| 31    | PBE      | <b>Pending Break Enable.</b> The processor supports the use of the FERR#/PBE# pin when the processor is in the stop-clock state (STPCLK# is asserted) to signal the processor that an interrupt is pending and that the processor should return to normal operation to handle the interrupt. Bit 10 (PBE enable) in the IA32_MISC_ENABLE MSR enables this capability. |

**INPUT EAX = 2: Cache and TLB Information Returned in EAX, EBX, ECX, EDX**

When CPUID executes with EAX set to 2, the processor returns information about the processor's internal caches and TLBs in the EAX, EBX, ECX, and EDX registers.

The encoding is as follows:

- The least-significant byte in register EAX (register AL) indicates the number of times the CPUID instruction must be executed with an input value of 2 to get a complete description of the processor's caches and TLBs. The first member of the family of Pentium 4 processors will return a 1.
- The most significant bit (bit 31) of each register indicates whether the register contains valid information (set to 0) or is reserved (set to 1).
- If a register contains valid information, the information is contained in 1 byte descriptors. Table 2-24 shows the encoding of these descriptors. Note that the order of descriptors in the EAX, EBX, ECX, and EDX registers is not defined; that is, specific bytes are not designated to contain descriptors for specific cache or TLB types. The descriptors may appear in any order.

**Table 2-24. Encoding of Cache and TLB Descriptors**

| Descriptor Value | Cache or TLB Description  |
|------------------|---|
| 00H              | Null descriptor   |
| 01H              | Instruction TLB: 4 KByte pages, 4-way set associative, 32 entries |
| 02H              | Instruction TLB: 4 MByte pages, 4-way set associative, 2 entries  |

**Table 2-24. Encoding of Cache and TLB Descriptors (Continued)**

| Descriptor Value | Cache or TLB Description   |
|------------------|--|
| 03H              | Data TLB: 4 KByte pages, 4-way set associative, 64 entries   |
| 04H              | Data TLB: 4 MByte pages, 4-way set associative, 8 entries  |
| 05H              | Data TLB1: 4 MByte pages, 4-way set associative, 32 entries  |
| 06H              | 1st-level instruction cache: 8 KBytes, 4-way set associative, 32 byte line size  |
| 08H              | 1st-level instruction cache: 16 KBytes, 4-way set associative, 32 byte line size   |
| 0AH              | 1st-level data cache: 8 KBytes, 2-way set associative, 32 byte line size   |
| 0BH              | Instruction TLB: 4 MByte pages, 4-way set associative, 4 entries   |
| 0CH              | 1st-level data cache: 16 KBytes, 4-way set associative, 32 byte line size  |
| 22H              | 3rd-level cache: 512 KBytes, 4-way set associative, 64 byte line size, 2 lines per sector  |
| 23H              | 3rd-level cache: 1 MBytes, 8-way set associative, 64 byte line size, 2 lines per sector  |
| 25H              | 3rd-level cache: 2 MBytes, 8-way set associative, 64 byte line size, 2 lines per sector  |
| 29H              | 3rd-level cache: 4 MBytes, 8-way set associative, 64 byte line size, 2 lines per sector  |
| 2CH              | 1st-level data cache: 32 KBytes, 8-way set associative, 64 byte line size  |
| 30H              | 1st-level instruction cache: 32 KBytes, 8-way set associative, 64 byte line size   |
| 40H              | No 2nd-level cache or, if processor contains a valid 2nd-level cache, no 3rd-level cache   |
| 41H              | 2nd-level cache: 128 KBytes, 4-way set associative, 32 byte line size  |
| 42H              | 2nd-level cache: 256 KBytes, 4-way set associative, 32 byte line size  |
| 43H              | 2nd-level cache: 512 KBytes, 4-way set associative, 32 byte line size  |
| 44H              | 2nd-level cache: 1 MByte, 4-way set associative, 32 byte line size   |
| 45H              | 2nd-level cache: 2 MByte, 4-way set associative, 32 byte line size   |
| 46H              | 3rd-level cache: 4 MByte, 4-way set associative, 64 byte line size   |
| 47H              | 3rd-level cache: 8 MByte, 8-way set associative, 64 byte line size   |
| 49H              | 3rd-level cache: 4MB, 16-way set associative, 64-byte line size (Intel Xeon processor MP, Family 0FH, Model 06H);<br>2nd-level cache: 4 MByte, 16-way set associative, 64 byte line size |
| 4AH              | 3rd-level cache: 6MByte, 12-way set associative, 64 byte line size   |
| 4BH              | 3rd-level cache: 8MByte, 16-way set associative, 64 byte line size   |

| B0H              | Instruction TLB: 4 KByte pages, 4-way set associative, 128 entries                       |

**Table 2-24. Encoding of Cache and TLB Descriptors (Continued)**

| Descriptor Value | Cache or TLB Description  |
|------------------|---|
| B1H              | Instruction TLB: 2M pages, 4-way, 8 entries or 4M pages, 4-way, 4 entries |
| B3H              | Data TLB: 4 KByte pages, 4-way set associative, 128 entries               |
| B4H              | Data TLB1: 4 KByte pages, 4-way associative, 256 entries                  |
| F0H              | 64-Byte prefetching   |
| F1H              | 128-Byte prefetching  |

**Example 2-1. Example of Cache and TLB Interpretation**

The first member of the family of Pentium 4 processors returns the following information about caches and TLBs when the CPUID executes with an input value of 2:

```
EAX    66 5B 50 01H
EBX    0H
ECX    0H
EDX    00 7A 70 00H
```

Which means:

- The least-significant byte (byte 0) of register EAX is set to 01H. This indicates that CPUID needs to be executed once with an input value of 2 to retrieve complete information about caches and TLBs.
- The most-significant bit of all four registers (EAX, EBX, ECX, and EDX) is set to 0, indicating that each register contains valid 1-byte descriptors.
- Bytes 1, 2, and 3 of register EAX indicate that the processor has:
  - 50H - a 64-entry instruction TLB, for mapping 4-KByte and 2-MByte or 4-MByte pages.
  - 5BH - a 64-entry data TLB, for mapping 4-KByte and 4-MByte pages.
  - 66H - an 8-KByte 1st level data cache, 4-way set associative, with a 64-Byte cache line size.
- The descriptors in registers EBX and ECX are valid, but contain NULL descriptors.
- Bytes 0, 1, 2, and 3 of register EDX indicate that the processor has:
  - 00H - NULL descriptor.
  - 70H - Trace cache: 12 K- $\mu$ op, 8-way set associative.
  - 7AH - a 256-KByte 2nd level cache, 8-way set associative, with a sectored, 64-byte cache line size.
  - 00H - NULL descriptor.

### **INPUT EAX = 4: Returns Deterministic Cache Parameters for Each Level**

When CPUID executes with EAX set to 4 and ECX contains an index value, the processor returns encoded data that describe a set of deterministic cache parameters (for the cache level associated with the input in ECX). Valid index values start from 0.

Software can enumerate the deterministic cache parameters for each level of the cache hierarchy starting with an index value of 0, until the parameters report the value associated with the cache type field is 0. The architecturally defined fields reported by deterministic cache parameters are documented in Table 2-19.

The CPUID leaf 4 also reports data that can be used to derive the topology of processor cores in a physical package. This information is constant for all valid index values. Software can query the raw data reported by executing CPUID with EAX=4 and ECX=0 and use it as part of the topology enumeration algorithm described in Chapter 8, “Multiple-Processor Management,” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

### **INPUT EAX = 5: Returns MONITOR and MWAIT Features**

When CPUID executes with EAX set to 5, the processor returns information about features available to MONITOR/MWAIT instructions. The MONITOR instruction is used for address-range monitoring in conjunction with MWAIT instruction. The MWAIT instruction optionally provides additional extensions for advanced power management. See Table 2-19.

### **INPUT EAX = 6: Returns Thermal and Power Management Features**

When CPUID executes with EAX set to 6, the processor returns information about thermal and power management features. See Table 2-19.

### **INPUT EAX = 7: Returns Structured Extended Feature Enumeration Information**

When CPUID executes with EAX set to 7 and ECX = 0, the processor returns information about the maximum number of sub-leaves that contain extended feature flags. See Table 2-19.

When CPUID executes with EAX set to 7 and ECX = n (n > 1 and less than the number of non-zero bits in CPUID.(EAX=07H, ECX= 0H).EAX, the processor returns information about extended feature flags. See Table 2-19. In subleaf 0, only EAX has the number of subleaves. In subleaf 0, EBX, ECX & EDX all contain extended feature flags.

**Table 2-25. Structured Extended Feature Leaf, Function 0, EBX Register**

| Bit # | Mnemonic   | Description   |
|-------|------------|---|
| 0     | RWFSGSBASE | A value of 1 indicates the processor supports RD/WR FSGSBASE instructions |
| 1-31  | Reserved   | Reserved  |

**INPUT EAX = 9: Returns Direct Cache Access Information**

When CPUID executes with EAX set to 9, the processor returns information about Direct Cache Access capabilities. See Table 2-19.

**INPUT EAX = 10: Returns Architectural Performance Monitoring Features**

When CPUID executes with EAX set to 10, the processor returns information about support for architectural performance monitoring capabilities. Architectural performance monitoring is supported if the version ID (see Table 2-19) is greater than Pn 0. See Table 2-19.

For each version of architectural performance monitoring capability, software must enumerate this leaf to discover the programming facilities and the architectural performance events available in the processor. The details are described in Chapter 16, "Debugging, Branch Profiles and Time-Stamp Counter," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.

**INPUT EAX = 11: Returns Extended Topology Information**

When CPUID executes with EAX set to 11, the processor returns information about extended topology enumeration data. Software must detect the presence of CPUID leaf 0BH by verifying (a) the highest leaf index supported by CPUID is  $\geq 0BH$ , and (b) CPUID.0BH:EBX[15:0] reports a non-zero value.

**INPUT EAX = 13: Returns Processor Extended States Enumeration Information**

When CPUID executes with EAX set to 13 and ECX = 0, the processor returns information about the bit-vector representation of all processor state extensions that are supported in the processor and storage size requirements of the XSAVE/XRSTOR area. See Table 2-19.

When CPUID executes with EAX set to 13 and ECX = n (n > 1 and less than the number of non-zero bits in CPUID.(EAX=0DH, ECX= 0H).EAX and CPUID.(EAX=0DH, ECX= 0H).EDX), the processor returns information about the size and offset of each processor extended state save area within the XSAVE/XRSTOR area. See Table 2-19.

**METHODS FOR RETURNING BRANDING INFORMATION**

Use the following techniques to access branding information:

1. Processor brand string method; this method also returns the processor's maximum operating frequency
2. Processor brand index; this method uses a software supplied brand string table.

These two methods are discussed in the following sections. For methods that are available in early processors, see Section: "Identification of Earlier IA-32 Processors" in Chapter 14 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*.

### The Processor Brand String Method

Figure 2-5 describes the algorithm used for detection of the brand string. Processor brand identification software should execute this algorithm on all Intel 64 and IA-32 processors.

This method (introduced with Pentium 4 processors) returns an ASCII brand identification string and the maximum operating frequency of the processor to the EAX, EBX, ECX, and EDX registers.

**Figure 2-5. Determination of Support for the Processor Brand String**

### How Brand Strings Work

To use the brand string method, execute CPUID with EAX input of 8000002H through 8000004H. For each input value, CPUID returns 16 ASCII characters using EAX, EBX, ECX, and EDX. The returned string will be NULL-terminated.

Table 2-26 shows the brand string that is returned by the first processor in the Pentium 4 processor family.

**Table 2-26. Processor Brand String Returned with Pentium 4 Processor**

| <b>EAX Input Value</b> | <b>Return Values</b>   | <b>ASCII Equivalent</b>               |
|------------------------|--|---------------------------------------|
| 80000002H              | EAX = 20202020H<br>EBX = 20202020H<br>ECX = 20202020H<br>EDX = 6E492020H | " "<br>" "<br>" "<br>"nl "            |
| 80000003H              | EAX = 286C6574H<br>EBX = 50202952H<br>ECX = 69746E65H<br>EDX = 52286D75H | "(let"<br>"P)R"<br>"itne"<br>"R(mu"   |
| 80000004H              | EAX = 20342029H<br>EBX = 20555043H<br>ECX = 30303531H<br>EDX = 007A484DH | " 4 )"<br>" UPC"<br>"0051"<br>"\0zHM" |

### Extracting the Maximum Processor Frequency from Brand Strings

Figure 2-6 provides an algorithm which software can use to extract the maximum processor operating frequency from the processor brand string.

#### NOTE

When a frequency is given in a brand string, it is the maximum qualified frequency of the processor, not the frequency at which the processor is currently running.

**Figure 2-6. Algorithm for Extracting Maximum Processor Frequency**

### The Processor Brand Index Method

The brand index method (introduced with Pentium<sup>®</sup> III Xeon<sup>®</sup> processors) provides an entry point into a brand identification table that is maintained in memory by system software and is accessible from system- and user-level code. In this table, each brand index is associated with an ASCII brand identification string that identifies the official Intel family and model number of a processor.

When CPUID executes with EAX set to 1, the processor returns a brand index to the low byte in EBX. Software can then use this index to locate the brand identification string for the processor in the brand identification table. The first entry (brand index 0) in this table is reserved, allowing for backward compatibility with processors that

do not support the brand identification feature. Starting with processor signature family ID = 0FH, model = 03H, brand index method is no longer supported. Use brand string method instead.

Table 2-27 shows brand indices that have identification strings associated with them.

**Table 2-27. Mapping of Brand Indices; and Intel 64 and IA-32 Processor Brand Strings**

| Brand Index | Brand String  |
|-------------|---|
| 00H         | This processor does not support the brand identification feature  |
| 01H         | Intel(R) Celeron(R) processor <sup>1</sup>  |
| 02H         | Intel(R) Pentium(R) III processor <sup>1</sup>  |
| 03H         | Intel(R) Pentium(R) III Xeon(R) processor; If processor signature = 000006B1h, then Intel(R) Celeron(R) processor |

### Flags Affected

None.

## Exceptions (All Operating Modes)

#UD

If the LOCK prefix is used.

In earlier IA-32 processors that do not support the CUID instruction, execution of the instruction results in an invalid opcode (#UD) exception being generated.

## CHAPTER 3

# SYSTEM PROGRAMMING MODEL

---

This chapter describes the operating system programming considerations for AVX. The AES extension and PCLMULQDQ instruction follow the same system software requirements for XMM state support and SIMD floating-point exception support as SSE2, SSE3, SSSE3, SSE4 (see Chapter 12 of *IA-32 Intel Architecture Software Developer's Manual, Volumes 3A*).

The AVX and FMA extensions operate on 256-bit YMM registers, and require operating system to supports processor extended state management using XSAVE/XRSTOR instructions. VAESDEC/VAESDECLAST/VAESENC/VAESENCLAST/VAESIMC/VAESKEYGENASSIST/VPCLMULQDQ follow the same system programming requirements as AVX and FMA instructions operating on YMM states.

The basic requirements for an operating system using XSAVE/XRSTOR to manage processor extended states for current and future Intel Architecture processors can be found in Chapter 12 of *IA-32 Intel Architecture Software Developer's Manual, Volumes 3A*. This chapter covers additional requirements for OS to support YMM state.

### 3.1 YMM STATE, VEX PREFIX AND SUPPORTED OPERATING MODES

AVX and FMA instructions comprises of 256-bit and 128-bit instructions that operates on YMM states via VEX prefix encoding. SIMD instructions operating on XMM states (i.e. not accessing the upper 128 bits of YMM) generally do not use VEX prefix.

For processors that support YMM states, the YMM state exists in all operating modes. However, the available interfaces to access YMM states may vary in different modes. The processor's support for instruction extensions that employ VEX prefix encoding is independent of the processor's support for YMM state.

Instructions requiring VEX prefix encoding generally are supported in 64-bit, 32-bit modes, and 16-bit protected mode. They are not supported in Real mode, Virtual-8086 mode or entering into SMM mode.

Note that bits 255:128 of YMM register state are maintained across transitions into and out of these modes. Because, XSAVE/XRSTOR instruction can operate in all operating modes, it is possible that the processor's YMM register state can be modified by software in any operating mode by executing XRSTOR. The YMM registers can be updated by XRSTOR using the state information stored in the XSAVE/XRSTOR area residing in memory.

## 3.2 YMM STATE MANAGEMENT

Operating systems must use the XSAVE/XRSTOR instructions for YMM state management. The XSAVE/XRSTOR instructions also provide flexible and efficient interface to manage XMM/MXCSR states and x87 FPU states in conjunction with new processor extended states.

An OS must enable its YMM state management to support AVX and FMA extensions. Otherwise, an attempt to execute an instruction in AVX or FMA extensions (including an enhanced 128-bit SIMD instructions using VEX encoding) will cause a #UD exception.

### 3.2.1 Detection of YMM State Support

Detection of hardware support for new processor extended state is provided by the main leaf of CPUID leaf function 0DH with index ECX = 0. Specifically, the return value in EDX:EAX of CPUID.(EAX=0DH, ECX=0) provides a 64-bit wide bit vector of hardware support of processor state components, beginning with bit 0 of EAX corresponding to x87 FPU state, CPUID.(EAX=0DH, ECX=0):EAX[1] corresponding to SSE state (XMM registers and MXCSR), CPUID.(EAX=0DH, ECX=0):EAX[2] corresponding to YMM states.

### 3.2.2 Enabling of YMM State

An OS can enable YMM state support with the following steps:

- Verify the processor supports XSAVE/XRSTOR/XSETBV/XGETBV instructions and the XFEATURE\_ENABLED\_MASK register by checking CPUID.1.ECX.XSAVE[bit 26]=1.
- Verify the processor supports YMM state (i.e. bit 2 of XFEATURE\_ENABLED\_MASK is valid) by checking CPUID.(EAX=0DH, ECX=0):EAX.YMM[2]. The OS should also verify CPUID.(EAX=0DH, ECX=0):EAX.SSE[bit 1]=1, because the lower 128-bits of an YMM register are aliased to an XMM register.

The OS must determine the buffer size requirement for the XSAVE area that will be used by XSAVE/XRSTOR (see CPUID instruction in Section 2.9).

- Set CR4.OSXSAVE[bit 18]=1 to enable the use of XSETBV/XGETBV instructions to write/read the XFEATURE\_ENABLED\_MASK register.
- Supply an appropriate mask via EDX:EAX to execute XSETBV to enable the processor state components that the OS wishes to manage using XSAVE/XRSTOR instruction. To enable x87 FPU, SSE and YMM state management using XSAVE/XRSTOR, the enable mask is EDX=0H, EAX=7H (The individual bits of XFEATURE\_ENABLED\_MASK is listed in Table 3-1).

To enable YMM state, the OS must use EDX:EAX[2:1] = 11B when executing XSETBV. An attempt to execute XSETBV with EDX:EAX[2:1] = 10B causes a #GP(0) exception.

**Table 3-1. XFEATURE\_ENABLED\_MASK and Processor State Components**

| Bit     | Meaning   |
|---------|---|
| 0 - x87 | If set, the processor supports x87 FPU state management via XSAVE/XRSTOR. This bit must be 1 if CPUID.01H:ECX.XSAVE[26] = 1.                        |
| 1 - SSE | If set, the processor supports SSE state (XMM and MXCSR) management via XSAVE/XRSTOR. This bit must be set to '1' to enable AVX.                    |
| 2 - YMM | If set, the processor supports YMM state (upper 128 bits of YMM registers) management via XSAVE. This bit must be set to '1' to enable AVX and FMA. |

### 3.2.3 Enabling of SIMD Floating-Exception Support

AVX and FMA instruction may generate SIMD floating-point exceptions. An OS must enable SIMD floating-point exception support by setting CR4.OSXMMEXCPT[bit 10]=1.

The effect of CR4 setting that affects AVX and FMA enabling is listed in Table 3-2

**Table 3-2. CR4 bits for AVX New Instructions technology support**

| Bit                    | Meaning   |
|------------------------|---|
| CR4.OSXSAVE[bit 18]    | If set, the OS supports use of XSETBV/XGETBV instruction to access the XFEATURE_ENABLED_MASK register, XSAVE/XRSTOR to manage processor extended state. Must be set to '1' to enable AVX and FMA. |
| CR4.OSXMMEXCPT[bit 10] | Must be set to 1 to enable SIMD floating-point exceptions. This applies to AVX, FMA operating on YMM states, and legacy 128-bit SIMD floating-point instructions operating on XMM states.         |
| CR4.OSFXSR[bit 9]      | Ignored by AVX and FMA instructions operating on YMM states. Must be set to 1 to enable SIMD instructions operating on XMM state.   |

### 3.2.4 The Layout of XSAVE Area

The OS must determine the buffer size requirement by querying CPUID with EAX=0DH, ECX=0. If the OS wishes to enable all processor extended state components in the XFEATURE\_ENABLED\_MASK, it can allocate the buffer size according to CPUID.(EAX=0DH, ECX=0):ECX.

After the memory buffer for XSAVE is allocated, the entire buffer must be cleared to zero prior to use by XSAVE.

For processors that support SSE and YMM states, the XSAVE area layout is listed in Table 3-3. The register fields of the first 512 byte of the XSAVE area are identical to those of the FXSAVE/FXRSTOR area.

**Table 3-3. Layout of XSAVE Area For Processor Supporting YMM State**

| Save Areas            | Offset (Byte)              | Size (Bytes)               |
|-----------------------|----------------------------|----------------------------|
| FPU/SSE SaveArea      | 0                          | 512                        |
| Header                | 512                        | 64                         |
| Ext_Save_Area_2 (YMM) | CPUID.(EAX=0DH, ECX=2):EBX | CPUID.(EAX=0DH, ECX=2):EAX |

The format of the header is as follows (see Table 3-4):

**Table 3-4. XSAVE Header Format**

| 15:8                    | 7:0                     | Byte Offset from Header | Byte Offset from XSAVE Area |
|-------------------------|-------------------------|-------------------------|-----------------------------|
| Reserved (Must be zero) | XSTATE_BV               | 0                       | 512                         |
| Reserved                | Reserved (Must be zero) | 16                      | 528                         |
| Reserved                | Reserved                | 32                      | 544                         |
| Reserved                | Reserved                | 48                      | 560                         |

The layout of the Ext\_Save\_Area[YMM] contains 16 of the upper 128-bits of the YMM registers, it is shown in Table 3-5.

**Table 3-5. XSAVE Save Area Layout for YMM State (Ext\_Save\_Area\_2)**

| 31 16          | 15 0           | Byte Offset from YMM_Save_Area | Byte Offset from XSAVE Area |
|----------------|----------------|--------------------------------|-----------------------------|
| YMM1[255:128]  | YMM0[255:128]  | 0                              | 576                         |
| YMM3[255:128]  | YMM2[255:128]  | 32                             | 608                         |
| YMM5[255:128]  | YMM4[255:128]  | 64                             | 640                         |
| YMM7[255:128]  | YMM6[255:128]  | 96                             | 672                         |
| YMM9[255:128]  | YMM8[255:128]  | 128                            | 704                         |
| YMM11[255:128] | YMM10[255:128] | 160                            | 736                         |
| YMM13[255:128] | YMM12[255:128] | 192                            | 768                         |
| YMM15[255:128] | YMM14[255:128] | 224                            | 800                         |

### 3.2.5 XSAVE/XRSTOR Interaction with YMM State and MXCSR

The processor's action as a result of executing XRSTOR, on the MXCSR, XMM and YMM registers, are listed in Table 3-6 (Both bit 1 and bit 2 of the XFEATURE\_ENABLED\_MASK register are presumed to be 1). The XMM registers may be initialized by the processor (See XRSTOR operation in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*). When the MXCSR register is updated from memory, reserved bit checking is enforced. The saving/restoring of MXCSR is bound to both the SSE state and YMM state. MXCSR save/restore will not be bound to any future states.

**Table 3-6. XRSTOR Action on MXCSR, XMM Registers, YMM Registers**

| EDX:EAX |       | XSATE_BV |       | MXCSR | YMM_H Registers | XMM Registers |
|---------|-------|----------|-------|-------|-----------------|---------------|
| Bit 2   | Bit 1 | Bit 2    | Bit 1 |       |                 |               |
| 0       | 0     | X        | X     | None  | None            | None          |

**Table 3-6. XRSTOR Action on MXCSR, XMM Registers, YMM Registers**

| EDX:EAX |       | XSATE_BV |       | MXCSR      | YMM_H Registers   | XMM Registers     |
|---------|-------|----------|-------|------------|-------------------|-------------------|
| Bit 2   | Bit 1 | Bit 2    | Bit 1 |            |                   |                   |
| 0       | 1     | X        | 0     | Load/Check | None              | Init by processor |
| 0       | 1     | X        | 1     | Load/Check | None              | Load              |
| 1       | 0     | 0        | X     | Load/Check | Init by processor | None              |
| 1       | 0     | 1        | X     | Load/Check | Load              | None              |
| 1       | 1     | 0        | 0     | Load/Check | Init by processor | Init by processor |
| 1       | 1     | 0        | 1     | Load/Check | Init by processor | Load              |
| 1       | 1     | 1        | 0     | Load/Check | Load              | Init by processor |
| 1       | 1     | 1        | 1     | Load/Check | Load              | Load              |

The processor supplied init values for each processor state component used by XRSTOR is listed in Table 3-7.

**Table 3-7. Processor Supplied Init Values XRSTOR May Use**

| Processor State Component | Processor Supplied Register Values  |
|---------------------------|---|
| x87 FPU State             | FCW ← 037FH; FTW ← 0FFFFH; FSW ← 0H; FPU CS ← 0H;<br>FPU DS ← 0H; FPU IP ← 0H; FPU DP ← 0; ST0-ST7 ← 0; |
| SSE State <sup>1</sup>    | If 64-bit Mode: XMM0-XMM15 ← 0H;<br>Else XMM0-XMM7 ← 0H   |
| YMM State <sup>1</sup>    | If 64-bit Mode: YMM0_H-YMM15_H ← 0H;<br>Else YMM0_H-YMM7_H ← 0H   |

**NOTES:**

1. MXCSR state is not updated by processor supplied values. MXCSR state can only be updated by XRSTOR from state information stored in XSAVE/XRSTOR area.

The action of XSAVE is listed in Table 3-8.

Table 3-8. XSAVE Action on MXCSR, XMM, YMM Register

| EDX:EAX |       | XFEATURE_ENABL<br>ED_MASK |       | MXCSR | YMM_H<br>Registers | XMM Registers |
|---------|-------|---------------------------|-------|-------|--------------------|---------------|
| Bit 2   | Bit 1 | Bit 2                     | Bit 1 |       |                    |               |
| 0       | 0     | X                         | X     | None  | None               | None          |
| 0       | 1     | X                         | 1     | Store | None               | Store         |
| 0       | 1     | X                         | 0     | None  | None               | None          |
| 1       | 0     | 0                         | X     | None  | None               | None          |
| 1       | 0     | 1                         | 1     | Store | Store              | None          |
| 1       | 1     | 0                         | 0     | None  | None               | None          |
| 1       | 1     | 0                         | 1     | Store | None               | Store         |
| 1       | 1     | 1                         | 1     | Store | Store              | Store         |

### 3.2.6 Processor Extended State Save Optimization and XSAVEOPT

The XSAVEOPT instruction paired with XRSTOR is designed to provide a high performance method for system software to perform state save and restore.

A processor may indicate its support for the XSAVEOPT instruction if CPUID.(EAX=0DH, ECX=1):EAX.XSAVEOPT[Bit 0] = 1. The functionality of XSAVEOPT is similar to XSAVE. Software can use XSAVEOPT/XRSTOR in a pair-wise manner similar to XSAVE/XRSTOR to save and restore processor extended states.

The syntax and operands for XSAVEOPT instructions are identical to XSAVE, i.e. the mask operand in EDX:EAX specifies the subset of enabled features to be saved.

Note that software using XSAVEOPT must observe the same restrictions as XSAVE while allocating a new save area. i.e., the header area must be initialized to zeroes. The first 64-bits in the save image header starting at offset 512 are referred to as XHEADER.BV. However, the instruction differs from XSAVE in several important aspects:

1. If a component state in the processor specified by the save mask corresponds to an INIT state, the instruction may clear the corresponding bit in XHEADER.BV, but may not write out the state (unlike the XSAVE instruction, which always writes out the state).
2. If the processor determines that the component state specified by the save mask hasn't been modified since the last XRSTOR, the instruction may not write out the state to the save area.
3. A implication of this optimization is that software which needs to examine the saved image must first check the XHEADER.BV to see if any bits are clear. If the

header bit is clear, it means that the state is INIT and the saved memory image may not correspond to the actual processor state.

4. The performance of XSAVEOPT will always be better than or at least equal to that of XSAVE.

### 3.2.6.1 XSAVEOPT Usage Guidelines

When using the XSAVEOPT facility, software must be aware of the following guidelines:

1. The processor uses a tracking mechanism to determine which state components will be written to memory by the XSAVEOPT instruction. The mechanism includes three sub-conditions that are recorded internally each time XRSTOR is executed and evaluated on the invocation of the next XSAVEOPT. If a change is detected in any one of these sub-conditions, XSAVEOPT will behave exactly as XSAVE. The three sub-conditions are:
  - current CPL of the logical processor
  - indication whether or not the logical processor is in VMX non-root operation
  - linear address of the XSAVE/XRSTOR area
2. Upon allocation of a new XSAVE/XRSTOR area and before an XSAVE or XSAVEOPT instruction is used, the save area header (HEADER.XSTATE) must be initialized to zeroes for proper operation.
3. XSAVEOPT is designed primarily for use in context switch operations. The values stored by the XSAVEOPT instruction depend on the values previously stored in a given XSAVE area.
4. Manual modifications to the XSAVE area between an XRSTOR instruction and the matching XSAVEOPT may result in data corruption.
5. For optimization to be performed properly, the XRSTOR XSAVEOPT pair must use the same segment when referencing the XSAVE area and the base of that segment must be unchanged between the two operations.
6. Software should avoid executing XSAVEOPT into a buffer from which it hadn't previously executed a XRSTOR. For newly allocated buffers, software can execute XRSTOR with the linear address of the buffer and a restore mask of EDX:EAX = 0. Executing XRSTOR(0:0) doesn't restore any state, but ensures expected operation of the XSAVEOPT instruction.
7. The XSAVE area can be moved or even paged, but the contents at the linear address of the save area at an XSAVEOPT must be the same as that when the previous XRSTOR was performed.

A destination operand not aligned to 64-byte boundary (in either 64-bit or 32-bit modes) will result in a general-protection (#GP) exception being generated. In 64-bit mode, the upper 32 bits of RDX and RAX are ignored.

### 3.3 RESET BEHAVIOR

At processor reset

- YMM0-16 bits[255:0] are set to zero.
- XFEATURE\_ENABLED\_MASK[2:1] is set to zero, XFEATURE\_ENABLED\_MASK[0] is set to 1.
- CR4.OSXSAVE[bit 18] (and its mirror CPUID.1.ECX.OSXSAVE[bit 27]) is set to 0.

### 3.4 EMULATION

Setting the CR0.EMbit to 1 provides a technique to emulate Legacy SSE floating-point instruction sets in software. This technique is not supported with AVX instructions, nor FMA instructions.

If an operating system wishes to emulate AVX instructions, set XFEATURE\_ENABLED\_MASK[2:1] to zero. This will cause AVX instructions to #UD. Emulation of FMA by operating system can be done similarly as with emulating AVX instructions.

### 3.5 WRITING AVX FLOATING-POINT EXCEPTION HANDLERS

AVX and FMA floating-point exceptions are handled in an entirely analogous way to Legacy SSE floating-point exceptions. To handle unmasked SIMD floating-point exceptions, the operating system or executive must provide an exception handler. The section titled "SSE and SSE2 SIMD Floating-Point Exceptions" in Chapter 11, "Programming with Streaming SIMD Extensions 2 (SSE2)," of the *IA-32 Intel® Architecture Software Developer's Manual, Volume 1*, describes the SIMD floating-point exception classes and gives suggestions for writing an exception handler to handle them.

To indicate that the operating system provides a handler for SIMD floating-point exceptions (#XM), the CR4.OSXMMEXCPT flag (bit 10) must be set.

This page was intentionally left blank.

§

## CHAPTER 4

# INSTRUCTION FORMAT

---

AVX and FMA instructions are encoded using a more efficient format than previous instruction extensions in the Intel 64 and IA-32 architecture. The improved encoding format uses a new prefix referred to as "VEX". The VEX prefix may be two or three bytes long, depending on the instruction semantics. Despite the length of the VEX prefix, the instruction encoding format using VEX addresses two important issues: (a) there exists inefficiency in instruction encoding due to SIMD prefixes and some fields of the REX prefix, (b) Both SIMD prefixes and REX prefix increase in instruction byte-length. This chapter describes the instruction encoding format using VEX.

## 4.1 INSTRUCTION FORMATS

Legacy instruction set extensions in IA-32 architecture employs one or more "single-purpose" byte as an "escape opcode", or required SIMD prefix (66H, F2H, F3H) to expand the processing capability of the instruction set. Intel 64 architecture uses the REX prefix to expand the encoding of register access in instruction operands. Both SIMD prefixes and REX prefix carry the side effect that they can cause the length of an instruction to increase significantly. Legacy Intel 64 and IA-32 instruction set are limited to supporting instruction syntax of only two operands that can be encoded to access registers (and only one can access a memory address).

Instruction encoding using VEX prefix provides several advantages:

- Instruction syntax support for three operands and up-to four operands when necessary. For example, the third source register used by VBLENDVPD is encoded using bits 7:4 of the immediate byte.
- Encoding support for vector length of 128 bits (using XMM registers) and 256 bits (using YMM registers)
- Encoding support for instruction syntax of non-destructive source operands.
- Elimination of escape opcode byte (0FH), SIMD prefix byte (66H, F2H, F3H) via a compact bit field representation within the VEX prefix.
- Elimination of the need to use REX prefix to encode the extended half of general-purpose register sets (R8-R15) for direct register access, memory addressing, or accessing XMM8-XMM15 (including YMM8-YMM15).
- Flexible and more compact bit fields are provided in the VEX prefix to retain the full functionality provided by REX prefix. REX.W, REX.X, REX.B functionalities are provided in the three-byte VEX prefix only because only a subset of SIMD instructions need them.
- Extensibility for future instruction extensions without significant instruction length increase.

## INSTRUCTION FORMAT

Figure 4-1 shows the Intel 64 instruction encoding format with VEX prefix support. Legacy instruction without a VEX prefix is fully supported and unchanged. The use of VEX prefix in an Intel 64 instruction is optional, but a VEX prefix is required for Intel 64 instructions that operate on YMM registers or support three and four operand syntax. VEX prefix is not a constant-valued, “single-purpose” byte like 0FH, 66H, F2H, F3H in legacy SSE instructions. VEX prefix provides substantially richer capability than the REX prefix.

Figure 4-1. Instruction Encoding Format with VEX Prefix

### 4.1.1 VEX and the LOCK prefix

Any VEX-encoded instruction with a LOCK prefix preceding VEX will #UD.

### 4.1.2 VEX and the 66H, F2H, and F3H prefixes

Any VEX-encoded instruction with a 66H, F2H, or F3H prefix preceding VEX will #UD.

### 4.1.3 VEX and the REX prefix

Any VEX-encoded instruction with a REX prefix proceeding VEX will #UD.

### 4.1.4 The VEX Prefix

The VEX prefix is encoded in either the two-byte form (the first byte must be C5H) or in the three-byte form (the first byte must be C4H). The two-byte VEX is used mainly for 128-bit, scalar, and the most common 256-bit AVX instructions; while the three-byte VEX provides a compact replacement of REX and 3-byte opcode instructions (including AVX and FMA instructions). Beyond the first byte of the VEX prefix, it consists of a number of bit fields providing specific capability, they are shown in Figure 4-2.

The bit fields of the VEX prefix can be summarized by its functional purposes:

- Non-destructive source register encoding (applicable to three and four operand syntax): This is the first source operand in the instruction syntax. It is represented by the notation, VEX.vvvv. This field is encoded using 1's

complement form (inverted form), i.e. XMM0/YMM0/R0 is encoded as 1111B, XMM15/YMM15/R15 is encoded as 0000B.

- Vector length encoding: This 1-bit field represented by the notation VEX.L. L= 0 means vector length is 128 bits wide, L=1 means 256 bit vector. The value of this field is written as VEX.128 or VEX.256 in this document to distinguish encoded values of other VEX bit fields.
- REX prefix functionality: Full REX prefix functionality is provided in the three-byte form of VEX prefix. However the VEX bit fields providing REX functionality are encoded using 1's complement form, i.e. XMM0/YMM0/R0 is encoded as 1111B, XMM15/YMM15/R15 is encoded as 0000B.
  - Two-byte form of the VEX prefix only provides the equivalent functionality of REX.R, using 1's complement encoding. This is represented as VEX.R.
  - Three-byte form of the VEX prefix provides REX.R, REX.X, REX.B functionality using 1's complement encoding and three dedicated bit fields represented as VEX.R, VEX.X, VEX.B.
  - Three-byte form of the VEX prefix provides the functionality of REX.W only to specific instructions that need to override default 32-bit operand size for a general purpose register to 64-bit size in 64-bit mode. For those applicable instructions, VEX.W field provides the same functionality as REX.W. VEX.W field can provide completely different functionality for other instructions.

Consequently, the use of REX prefix with VEX encoded instructions is not allowed. However, the intent of the REX prefix for expanding register set is reserved for future instruction set extensions using VEX prefix encoding format.

- Compaction of SIMD prefix: Legacy SSE instructions effectively use SIMD prefixes (66H, F2H, F3H) as an opcode extension field. VEX prefix encoding allows the functional capability of such legacy SSE instructions (operating on XMM registers, bits 255:128 of corresponding YMM unmodified) to be encoded using the VEX.pp field without the presence of any SIMD prefix. The VEX-encoded 128-bit instruction will zero-out bits 255:128 of the destination register. VEX-encoded instruction may have 128 bit vector length or 256 bits length.
- Compaction of two-byte and three-byte opcode: More recently introduced legacy SSE instructions employ two and three-byte opcode. The one or two leading bytes are: 0FH, and 0FH 3AH/0FH 38H. The one-byte escape (0FH) and two-byte escape (0FH 3AH, 0FH 38H) can also be interpreted as an opcode extension field. The VEX.mmmmm field provides compaction to allow many legacy instruction to be encoded without the constant byte sequence, 0FH, 0FH 3AH, 0FH 38H. These VEX-encoded instruction may have 128 bit vector length or 256 bits length.

The VEX prefix is required to be the last prefix and immediately precedes the opcode bytes. It must follow any other prefixes. If VEX prefix is present a REX prefix is not supported.

The 3-byte VEX leaves room for future expansion with 3 reserved bits. REX and the 66h/F2h/F3h prefixes are reclaimed for future use.

## INSTRUCTION FORMAT

VEX prefix has a two-byte form and a three byte form. If an instruction syntax can be encoded using the two-byte form, it can also be encoded using the three byte form of VEX. The latter increases the length of the instruction by one byte. This may be helpful in some situations for code alignment.

The VEX prefix supports 256-bit versions of floating-point SSE, SSE2, SSE3, and SSE4 instructions. Some additional support for 128-bit vector integer instructions is provided in Table A-1 of Appendix A. Note, certain new instruction functionality can only be encoded with the VEX prefix (See Appendix A, Table A-2).

The VEX prefix will #UD on any instruction containing MMX register sources or destinations.

- R: REX.R in 1's complement (inverted) form  
 1: Same as REX.R=0 (must be 1 in 32-bit mode)  
 0: Same as REX.R=1 (64-bit mode only)
- X: REX.X in 1's complement (inverted) form  
 1: Same as REX.X=0 (must be 1 in 32-bit mode)  
 0: Same as REX.X=1 (64-bit mode only)
- B: REX.B in 1's complement (inverted) form  
 1: Same as REX.B=0 (Ignored in 32-bit mode).  
 0: Same as REX.B=1 (64-bit mode only)
- W: opcode specific (use like REX.W, or used for opcode extension, or ignored, depending on the opcode byte)

m-mmmm:

- 00000: Reserved for future use (will #UD)
- 00001: implied 0F leading opcode byte
- 00010: implied 0F 38 leading opcode bytes
- 00011: implied 0F 3A leading opcode bytes
- 00100-11111: Reserved for future use (will #UD)

vvvv: a register specifier (in 1's complement form) or 1111 if unused.

L: Vector Length

- 0: scalar or 128-bit vector
- 1: 256-bit vector

pp: opcode extension providing equivalent functionality of a SIMD prefix

- 00: None
- 01: 66
- 10: F3
- 11: F2

Figure 4-2. VEX bitfields

The following subsections describe the various fields in two or three-byte VEX prefix:

### 4.1.4.1 VEX Byte 0, bits[7:0]

VEX Byte 0, bits [7:0] must contain the value 11000101b (C5h) or 11000100b (C4h). The 3-byte VEX uses the C4h first byte, while the 2-byte VEX uses the C5h first byte.

### 4.1.4.2 VEX Byte 1, bit [7] - 'R'

VEX Byte 1, bit [7] contains a bit analogous to a bit inverted REX.R. In protected and compatibility modes the bit must be set to '1' otherwise the instruction is LES or LDS. This bit is present in both 2- and 3-byte VEX prefixes.

The usage of WRXB bits for legacy instructions is explained in detail section 2.2.1.2 of Intel 64 and IA-32 Architectures Software developer's manual, Volume 2A.

This bit is stored in bit inverted format.

### 4.1.4.3 3-byte VEX byte 1, bit[6] - 'X'

Bit[6] of the 3-byte VEX byte 1 encodes a bit analogous to a bit inverted REX.X. It is an extension of the SIB Index field in 64-bit modes. In 32-bit modes, this bit must be set to '1' otherwise the instruction is LES or LDS.

This bit is available only in the 3-byte VEX prefix.

This bit is stored in bit inverted format.

### 4.1.4.4 3-byte VEX byte 1, bit[5] - 'B'

Bit[5] of the 3-byte VEX byte 1 encodes a bit analogous to a bit inverted REX.B. In 64-bit modes, it is an extension of the ModR/M r/m field, or the SIB base field. In 32-bit modes, this bit is ignored.

This bit is available only in the 3-byte VEX prefix.

This bit is stored in bit inverted format.

### 4.1.4.5 3-byte VEX byte 2, bit[7] - 'W'

Bit[7] of the 3-byte VEX byte 2 is represented by the notation VEX.W. It can provide following functions, depending on the specific opcode.

- For AVX instructions that have equivalent legacy SSE instructions (typically these SSE instructions have a general-purpose register operand with its operand size attribute promotable by REX.W), if REX.W promotes the operand size attribute of the general-purpose register operand in legacy SSE instruction, VEX.W has same meaning in the corresponding AVX equivalent form. In 32-bit

- modes, VEX.W is silently ignored.
- For AVX instructions that have equivalent legacy SSE instructions (typically these SSE instructions have operands with their operand size attribute fixed and not promotable by REX.W), if REX.W is don't care in legacy SSE instruction, VEX.W is ignored in the corresponding AVX equivalent form irrespective of mode.
  - For new AVX instructions where VEX.W has no defined function (typically these meant the combination of the opcode byte and VEX.mmmmm did not have any equivalent SSE functions), VEX.W is reserved as zero and setting to other than zero will cause instruction to #UD.

#### 4.1.4.6 2-byte VEX Byte 1, bits[6:3] and 3-byte VEX Byte 2, bits [6:3]- 'vvvv' the Source or dest Register Specifier

In 32-bit mode the VEX first byte C4 and C5 alias onto the LES and LDS instructions. To maintain compatibility with existing programs the VEX 2nd byte, bits [7:6] must be 11b. To achieve this, the VEX payload bits are selected to place only inverted, 64-bit valid fields (extended register selectors) in these upper bits.

The 2-byte VEX Byte 1, bits [6:3] and the 3-byte VEX, Byte 2, bits [6:3] encode a field (shorthand VEX.vvvv) that for instructions with 2 or more source registers and an XMM or YMM or memory destination encodes the first source register specifier stored in inverted (1's complement) form.

VEX.vvvv is not used by the instructions with one source (except certain shifts, see below) or on instructions with no XMM or YMM or memory destination. If an instruction does not use VEX.vvvv then it should be set to 1111b otherwise instruction will #UD.

In 64-bit mode all 4 bits may be used. See Table 4-1 for the encoding of the XMM or YMM registers. In 32-bit and 16-bit modes bit 6 must be 1 (if bit 6 is not 1, the 2-byte VEX version will generate LDS instruction and the 3-byte VEX version will ignore this bit).

**Table 4-1. VEX.vvvv to register name mapping**

| VEX.vvvv | Dest Register | Valid in Legacy/Compatibility 32-bit modes? |
|----------|---------------|---|
| 1111B    | XMM0/YMM0     | Valid                                       |
| 1110B    | XMM1/YMM1     | Valid                                       |
| 1101B    | XMM2/YMM2     | Valid                                       |
| 1100B    | XMM3/YMM3     | Valid                                       |
| 1011B    | XMM4/YMM4     | Valid                                       |
| 1010B    | XMM5/YMM5     | Valid                                       |
| 1001B    | XMM6/YMM6     | Valid                                       |
| 1000B    | XMM7/YMM7     | Valid                                       |
| 0111B    | XMM8/YMM8     | Invalid                                     |
| 0110B    | XMM9/YMM9     | Invalid                                     |
| 0101B    | XMM10/YMM10   | Invalid                                     |
| 0100B    | XMM11/YMM11   | Invalid                                     |
| 0011B    | XMM12/YMM12   | Invalid                                     |
| 0010B    | XMM13/YMM13   | Invalid                                     |
| 0001B    | XMM14/YMM14   | Invalid                                     |
| 0000B    | XMM15/YMM15   | Invalid                                     |

The VEX.vvvv field is encoded in bit inverted format for accessing a register operand.

#### 4.1.5 Instruction Operand Encoding and VEX.vvvv, ModR/M

VEX-encoded instructions support three-operand and four-operand instruction syntax. Some VEX-encoded instructions have syntax with less than three operands, e.g. VEX-encoded pack shift instructions support one source operand and one destination operand).

The roles of VEX.vvvv, reg field of ModR/M byte (ModR/M.reg), r/m field of ModR/M byte (ModR/M.r/m) with respect to encoding destination and source operands vary with different type of instruction syntax.

The role of VEX.vvvv can be summarized to three situations:

- VEX.vvvv encodes the first source register operand, specified in inverted (1's complement) form and is valid for instructions with 2 or more source operands.
- VEX.vvvv encodes the destination register operand, specified in 1's complement form for certain vector shifts. The instructions where VEX.vvvv is used as a destination are listed in Table 4-2. The notation in the "Opcode" column in Table 4-2 is described in detail in section 5.1.1

- VEX.vvvv does not encode any operand, the field is reserved and should contain 1111b.

**Table 4-2. Instructions with a VEX.vvvv destination**

| Opcode                     | Instruction mnemonic     |
|----------------------------|--------------------------|
| VEX.NDD.128.66.0F 73 /7 ib | VPSLLDQ xmm1, xmm2, imm8 |
| VEX.NDD.128.66.0F 73 /3 ib | VPSRLDQ xmm1, xmm2, imm8 |
| VEX.NDD.128.66.0F 71 /2 ib | VPSRLW xmm1, xmm2, imm8  |
| VEX.NDD.128.66.0F 72 /2 ib | VPSRLD xmm1, xmm2, imm8  |
| VEX.NDD.128.66.0F 73 /2 ib | VPSRLQ xmm1, xmm2, imm8  |
| VEX.NDD.128.66.0F 71 /4 ib | VPSRAW xmm1, xmm2, imm8  |
| VEX.NDD.128.66.0F 72 /4 ib | VPSRAD xmm1, xmm2, imm8  |
| VEX.NDD.128.66.0F 71 /6 ib | VPSLLW xmm1, xmm2, imm8  |
| VEX.NDD.128.66.0F 72 /6 ib | VPSLLD xmm1, xmm2, imm8  |
| VEX.NDD.128.66.0F 73 /6 ib | VPSLLQ xmm1, xmm2, imm8  |

The role of ModR/M.r/m field can be summarized to two situations:

- ModR/M.r/m encodes the instruction operand that references a memory address.
- For some instructions that do not support memory addressing semantics, ModR/M.r/m encodes either the destination register operand or a source register operand.

The role of ModR/M.reg field can be summarized to two situations:

- ModR/M.reg encodes either the destination register operand or a source register operand.
- For some instructions, ModR/M.reg is treated as an opcode extension and not used to encode any instruction operand.

For instruction syntax that support four operands, VEX.vvvv, ModR/M.r/m, ModR/M.reg encodes three of the four operands. The role of bits 7:4 of the immediate byte serves the following situation:

- Imm8[7:4] encodes the third source register operand.

#### 4.1.5.1 3-byte VEX byte 1, bits[4:0] - "m-mmmm"

Bits[4:0] of the 3-byte VEX byte 1 encode an implied leading opcode byte (0F, 0F 38, or 0F 3A). Several bits are reserved for future use and will #UD unless 0.

**Table 4-3. VEX.m-mmmm interpretation**

| VEX.m-mmmm   | Implied Leading Opcode Bytes |
|--------------|------------------------------|
| 00000B       | Reserved                     |
| 00001B       | 0F                           |
| 00010B       | 0F 38                        |
| 00011B       | 0F 3A                        |
| 00100-11111B | Reserved                     |
| (2-byte VEX) | 0F                           |

VEX.m-mmmm is only available on the 3-byte VEX. The 2-byte VEX implies a leading 0Fh opcode byte.

#### 4.1.5.2 2-byte VEX byte 1, bit[2], and 3-byte VEX byte 2, bit [2]- “L”

The vector length field, VEX.L, is encoded in bit[2] of either the second byte of 2-byte VEX, or the third byte of 3-byte VEX. If “VEX.L = 1”, it indicates 256-bit vector operation. “VEX.L = 0” indicates scalar and 128-bit vector operations.

The instruction VZEROUPPER is a special case that is encoded with VEX.L = 0, although its operation zero’s bits 255:128 of all YMM registers accessible in the current operating mode.

See the following table.

**Table 4-4. VEX.L interpretation**

| VEX.L | Vector Length                 |
|-------|-------------------------------|
| 0     | 128-bit (or 32/64-bit scalar) |
| 1     | 256-bit                       |

#### 4.1.5.3 2-byte VEX byte 1, bits[1:0], and 3-byte VEX byte 2, bits [1:0]- “pp”

Up to one implied prefix is encoded by bits[1:0] of either the 2-byte VEX byte 1 or the 3-byte VEX byte 2. The prefix behaves as if it was encoded prior to VEX, but after all other encoded prefixes.

See the following table.

**Table 4-5. VEX.pp interpretation**

| pp  | Implies this prefix after other prefixes but before VEX |
|-----|---|
| 00B | None  |
| 01B | 66  |
| 10B | F3  |
| 11B | F2  |

### 4.1.6 The Opcode Byte

One (and only one) opcode byte follows the 2 or 3 byte VEX. Legal opcodes are specified in Appendix B, in color. Any instruction that uses illegal opcode will #UD.

### 4.1.7 The MODRM, SIB, and Displacement Bytes

The encodings are unchanged but the interpretation of `reg_field` or `rm_field` differs (see above).

### 4.1.8 The Third Source Operand (Immediate Byte)

VEX-encoded instructions can support instruction with a four operand syntax. `VBLENDVPD`, `VBLENDVPS`, and `PBLENDVB` use `imm8[7:4]` to encode one of the source registers.

### 4.1.9 AVX Instructions and the Upper 128-bits of YMM registers

If an instruction with a destination XMM register is encoded with a VEX prefix, the processor zeroes the upper 128 bits of the equivalent YMM register. Legacy SSE instructions without VEX preserve the upper 128-bits.

#### 4.1.9.1 Vector Length Transition and Programming Considerations

An instruction encoded with a `VEX.128` prefix that loads a YMM register operand operates as follows:

- Data is loaded into bits 127:0 of the register
- Bits above bit 127 in the register are cleared.

Thus, such an instruction clears bits 255:128 of a destination YMM register on processors with a maximum vector-register width of 256 bits. In the event that future processors extend the vector registers to greater widths, an instruction encoded with a `VEX.128` or `VEX.256` prefix will also clear any bits beyond bit 255.

(This is in contrast with legacy SSE instructions, which have no VEX prefix; these modify only bits 127:0 of any destination register operand.)

Programmers should bear in mind that instructions encoded with VEX.128 and VEX.256 prefixes will clear any future extensions to the vector registers. A calling function that uses such extensions should save their state before calling legacy functions. This is not possible for involuntary calls (e.g., into an interrupt-service routine). It is recommended that software handling involuntary calls accommodate this by not executing instructions encoded with VEX.128 and VEX.256 prefixes. In the event that it is not possible or desirable to restrict these instructions, then software must take special care to avoid actions that would, on future processors, zero the upper bits of vector registers.

Processors that support further vector-register extensions (defining bits beyond bit 255) will also extend the XSAVE and XRSTOR instructions to save and restore these extensions. To ensure forward compatibility, software that handles involuntary calls and that uses instructions encoded with VEX.128 and VEX.256 prefixes should first save and then restore the vector registers (with any extensions) using the XSAVE and XRSTOR instructions with save/restore masks that set bits that correspond to all vector-register extensions. Ideally, software should rely on a mechanism that is cognizant of which bits to set. (E.g., an OS mechanism that sets the save/restore mask bits for all vector-register extensions that are enabled in XCR0.) Saving and restoring state with instructions other than XSAVE and XRSTOR will, on future processors with wider vector registers, corrupt the extended state of the vector registers - even if doing so functions correctly on processors supporting 256-bit vector registers. (The same is true if XSAVE and XRSTOR are used with a save/restore mask that does not set bits corresponding to all supported extensions to the vector registers.)

### 4.1.10 AVX Instruction Length

The AVX and FMA instructions described in this document (including VEX and ignoring other prefixes) do not exceed 11 bytes in length, but may increase in the future. The maximum length of an Intel 64 and IA-32 instruction remains 15 bytes.

## CHAPTER 5

# INSTRUCTION SET REFERENCE

---

Instructions that are described in this document follow the general documentation convention established in *Intel 64 and IA-32 Architectures Software Developer's Manual Volume 2A* and *2B*. Additional notations and conventions adopted in this document are listed in *Section 5.1*. *Section 5.2* covers supplemental information that applies to a specific subset of instructions.

## 5.1 INTERPRETING INSTRUCTION REFERENCE PAGES

This section describes the format of information contained in the instruction reference pages in this chapter. It explains notational conventions and abbreviations used in these sections that are outside of those conventions described in *Section 3.1* of the *Intel 64 and IA-32 Architectures Software Developer's Manual Volume 2A*.

### 5.1.1 Instruction Format

The following is an example of the format used for each instruction description in this chapter. The table below provides an example summary table:

## ADDSD- ADD Scalar Double-Precision Floating-Point Values (THIS IS AN EXAMPLE)

| Opcode/<br>Instruction                              | Op/<br>En | 64/32 bit<br>Mode<br>Support | CPUID<br>Feature<br>Flag | Description  |
|---|-----------|------------------------------|--------------------------|--|
| F2 0F 58 /r   | A         | V/V                          | SSE2                     | Add the low double-precision floating-point value from xmm2/mem to xmm1 and store the result in xmm1 |
| ADDSD xmm1, xmm2/m64<br>VEX.NDS.128.F2.0F.WIG 58 /r | B         | V/V                          | AVX                      | Add the low double-precision floating-point value from xmm3/mem to xmm2 and store the result in xmm1 |
| VADDSD xmm1, xmm2, xmm3/m64                         |           |                              |                          |  |

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3      | Operand4 |
|---|---------------|---------------|---------------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w) | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### 5.1.2 Opcode Column in the Instruction Summary Table

For notation and conventions applicable to instructions that do not use VEX prefix, consult *Section 3.1* of the *Intel 64 and IA-32 Architectures Software Developer's Manual Volume 2A*.

In the Instruction Summary Table, the Opcode column presents each instruction encoded using the VEX prefix in following form (including the modR/M byte if applicable, the immediate byte if applicable):

**VEX.[NDS].[128,256].[66,F2,F3].0F/0F3A/0F38.[W0,W1] opcode [/r] [/ib,/is4]**

- **VEX:** indicates the presence of the VEX prefix is required. The VEX prefix can be encoded using the three-byte form (the first byte is C4H), or using the two-byte form (the first byte is C5H). The two-byte form of VEX only applies to those instructions that do not require the following fields to be encoded:

VEX.mmmmm, VEX.W, VEX.X, VEX.B. Refer to Section 4.1.4 for more detail on the VEX prefix

The encoding of various sub-fields of the VEX prefix is described using the following notations:

- **NDS, NDD, DDS:** specifies that VEX.vvvv field is valid for the encoding of a register operand:
  - VEX.NDS: VEX.vvvv encodes the first source register in an instruction syntax where the content of source registers will be preserved.
  - VEX.NDD: VEX.vvvv encodes the destination register that cannot be encoded by ModR/M:reg field.
  - VEX.DDS: VEX.vvvv encodes the second source register in a three-operand instruction syntax where the content of first source register will be overwritten by the result.
  - If none of NDS, NDD, and DDS is present, VEX.vvvv must be 1111b (i.e. VEX.vvvv does not encode an operand). The VEX.vvvv field can be encoded using either the 2-byte or 3-byte form of the VEX prefix.
- **128,256:** VEX.L field can be 0 (denoted by VEX.128 or VEX.LZ) or 1 (denoted by VEX.256). The VEX.L field can be encoded using either the 2-byte or 3-byte form of the VEX prefix. The presence of the notation VEX.256 or VEX.128 in the opcode column should be interpreted as follows:
  - If VEX.256 is present in the opcode column: The semantics of the instruction must be encoded with VEX.L = 1. An attempt to encode this instruction with VEX.L = 0 can result in one of two situations: (a) if VEX.128 version is defined, the processor will behave according to the defined VEX.128 behavior; (b) an #UD occurs if there is no VEX.128 version defined.
  - If VEX.128 is present in the opcode column but there is no VEX.256 version defined for the same opcode byte: Two situations apply: (a) For VEX-encoded, 128-bit SIMD integer instructions, software must encode the instruction with VEX.L = 0. The processor will treat the opcode byte encoded with VEX.L = 1 by causing an #UD exception; (b) For VEX-encoded, 128-bit packed floating-point instructions, software must encode the instruction with VEX.L = 0. The processor will treat the opcode byte encoded with VEX.L = 1 by causing an #UD exception (e.g. VMOVLPS).
  - If VEX.LIG is present in the opcode column: The VEX.L value is ignored. This generally applies to VEX-encoded scalar SIMD floating-point instructions. Scalar SIMD floating-point instruction can be distinguished from the mnemonic of the instruction. Generally, the last two letters of the instruction mnemonic would be either "SS", "SD", or "SI" for SIMD floating-point conversion instructions.

- If VEX.LZ is present in the opcode column: The VEX.L must be encoded to be 0B, an #UD occurs if VEX.L is not zero.
- **66,F2,F3:** The presence or absence of these value maps to the VEX.pp field encodings. If absent, this corresponds to VEX.pp=00B. If present, the corresponding VEX.pp value affects the “opcode” byte in the same way as if a SIMD prefix (66H, F2H or F3H) does to the ensuing opcode byte. Thus a non-zero encoding of VEX.pp may be considered as an implied 66H/F2H/F3H prefix. The VEX.pp field may be encoded using either the 2-byte or 3-byte form of the VEX prefix.
- **0F,0F3A,0F38:** The presence maps to a valid encoding of the VEX.mmmmm field. Only three encoded values of VEX.mmmmm are defined as valid, corresponding to the escape byte sequence of 0FH, 0F3AH and 0F38H. The effect of a valid VEX.mmmmm encoding on the ensuing opcode byte is same as if the corresponding escape byte sequence on the ensuing opcode byte for non-VEX encoded instructions. Thus a valid encoding of VEX.mmmmm may be consider as an implies escape byte sequence of either 0FH, 0F3AH or 0F38H. The VEX.mmmmm field must be encoded using the 3-byte form of VEX prefix.
- **0F,0F3A,0F38 and 2-byte/3-byte VEX.** The presence of 0F3A and 0F38 in the opcode column implies that opcode can only be encoded by the three-byte form of VEX. The presence of 0F in the opcode column does not preclude the opcode to be encoded by the two-byte of VEX if the semantics of the opcode does not require any subfield of VEX not present in the two-byte form of the VEX prefix.
- **W0:** VEX.W=0.
- **W1:** VEX.W=1.
- The presence of W0/W1 in the opcode column applies to two situations: (a) it is treated as an extended opcode bit, (b) the instruction semantics support an operand size promotion to 64-bit of a general-purpose register operand or a 32-bit memory operand. The presence of W1 in the opcode column implies the opcode must be encoded using the 3-byte form of the VEX prefix. The presence of W0 in the opcode column does not preclude the opcode to be encoded using the C5H form of the VEX prefix, if the semantics of the opcode does not require other VEX subfields not present in the two-byte form of the VEX prefix. Please see Section 4.1.4 on the subfield definitions within VEX.
- **WIG:** If WIG is present, the instruction may be encoded using the C5H form (if VEX.mmmmm is not required); or when using the C4H form of VEX prefix, VEX.W value is ignored.
- **opcode:** Instruction opcode.
- **/is4:** An 8-bit immediate byte is present containing a source register specifier in imm[7:4] and instruction-specific payload in imm[3:0].
- **imz2:** Part of the is4 immediate byte providing control functions that apply to two-source permute instructions

- In general, the encoding of VEX.R, VEX.X, VEX.B fields are not shown explicitly in the opcode column. The encoding scheme of VEX.R, VEX.X, VEX.B fields must follow the rules defined in Section 4.1.4.

### 5.1.3 Instruction Column in the Instruction Summary Table

<additions to the eponymous PRM section>

- **ymm** — a YMM register. The 256-bit YMM registers are: YMM0 through YMM7; YMM8 through YMM15 are available in 64-bit mode.
- **m256** — A 32-byte operand in memory. This nomenclature is used only with AVX and FMA instructions.
- **ymm/m256** - a YMM register or 256-bit memory operand.
- **<YMM0>**: indicates use of the YMM0 register as an implicit argument.
- **SRC1** - Denotes the first source operand in the instruction syntax of an instruction encoded with the VEX prefix and having two or more source operands.
- **SRC2** - Denotes the second source operand in the instruction syntax of an instruction encoded with the VEX prefix and having two or more source operands.
- **SRC3** - Denotes the third source operand in the instruction syntax of an instruction encoded with the VEX prefix and having three source operands.
- **SRC** - The source in a AVX single-source instruction or the source in a Legacy SSE instruction.
- **DST** - the destination in a AVX instruction. In Legacy SSE instructions can be either the destination, first source, or both. This field is encoded by `reg_field`.

### 5.1.4 Operand Encoding column in the Instruction Summary Table

The “operand encoding” column is abbreviated as Op/En in the Instruction Summary table heading. Each entry corresponds to a specific instruction syntax in the immediate column to its left and points to a corresponding row in a separate instruction operand encoding table immediately following the instruction summary table. The operand encoding table in each instruction reference page lists each instruction operand (according to each instruction syntax and operand ordering shown in the instruction column) relative to the ModRM byte, VEX.vvvv field or additional operand encoding placement.

### 5.1.5 64/32 bit Mode Support column in the Instruction Summary Table

The “64/32 bit Mode Support” column in the Instruction Summary table indicates whether an opcode sequence is supported in (a) 64-bit mode or (b) the Compatibility

mode and other IA-32 modes that apply in conjunction with the CPUID feature flag associated specific instruction extensions.

The 64-bit mode support is to the left of the 'slash' and has the following notation:

- **V** — Supported.
- **I** — Not supported.
- **N.E.** — Indicates an instruction syntax is not encodable in 64-bit mode (it may represent part of a sequence of valid instructions in other modes).
- **N.P.** — Indicates the REX prefix does not affect the legacy instruction in 64-bit-mode.
- **N.I.** — Indicates the opcode is treated as a new instruction in 64-bit mode.
- **N.S.** — Indicates an instruction syntax that requires an address override prefix in 64-bit mode and is not supported. Using an address override prefix in 64-bit mode may result in model-specific execution behavior.

The compatibility/Legacy mode support is to the right of the 'slash' and has the following notation:

- **V** — Supported.
- **I** — Not supported.
- **N.E.** — Indicates an Intel 64 instruction mnemonics/syntax that is not encodable; the opcode sequence is not applicable as an individual instruction in compatibility mode or IA-32 mode. The opcode may represent a valid sequence of legacy IA-32 instructions.

### 5.1.6 CPUID Support column in the Instruction Summary Table

The fourth column holds abbreviated CPUID feature flags (e.g. appropriate bit in CPUID.1.ECX, CPUID.1.EDX for SSE/SSE2/SSE3/SSSE3/SSE4.1/SSE4.2/AVX support) that indicate processor support for the instruction. If the corresponding flag is '0', the instruction will #UD.

## 5.2 AES TRANSFORMATIONS AND DATA STRUCTURE

### 5.2.1 Little-Endian Architecture and Big-Endian Specification (FIPS 197)

FIPS 197 document defines the Advanced Encryption Standard (AES) and includes a set of test vectors for testing all of the steps in the algorithm, and can be used for testing and debugging.

The following observation is important for using the AES instructions offered in Intel 64 Architecture: FIPS 197 text convention is to write hex strings with the low-

memory byte on the left and the high-memory byte on the right. Intel's convention is the reverse. It is similar to the difference between Big Endian and Little Endian notations.

In other words, a 128 bits vector in the FIPS document, when read from left to right, is encoded as [7:0, 15:8, 23:16, 31:24, ...127:120]. Note that inside the byte, the encoding is [7:0], so the first bit from the left is the most significant bit. In practice, the test vectors are written in hexadecimal notation, where pairs of hexadecimal digits define the different bytes. To translate the FIPS 197 notation to an Intel 64 architecture compatible ("Little Endian") format, each test vector needs to be byte-reflected to [127:120,... 31:24, 23:16, 15:8, 7:0].

Example A:

FIPS Test vector:       0x000102030405060708090a0b0c0d0e0f

Intel AES Hardware:   0x0f0e0d0c0b0a09080706050403020100

It should be pointed out that the only thing at issue is a textual convention, and programmers do not need to perform byte-reversal in their code, when using the AES instructions.

### 5.2.1.1 AES Data Structure in Intel 64 Architecture

The AES instructions that are defined in this document operate on one or on two 128 bits source operands: State and Round Key. From the architectural point of view, the state is input in an xmm register and the Round key is input either in an xmm register or a 128-bit memory location.

In AES algorithm, the state (128 bits) can be viewed as 4 32-bit doublewords ("Word"s in AES terminology): X3, X2, X1, X0.

The state may also be viewed as a set of 16 bytes. The 16 bytes can also be viewed as a 4x4 matrix of bytes where S(i, j) with i, j = 0, 1, 2, 3 compose the 32-bit "word"s as follows:

X0 = S (3, 0) S (2, 0) S (1, 0) S (0, 0)

X1 = S (3, 1) S (2, 1) S (1, 1) S (0, 1)

X2 = S (3, 2) S (2, 2) S (1, 2) S (0, 2)

X3 = S (3, 3) S (2, 3) S (1, 3) S (0, 3)

The following tables, Table 5-1 through Table 5-4, illustrate various representations of a 128-bit state.

Table 5-1. Byte and 32-bit Word Representation of a 128-bit State

|              |            |            |            |            |            |            |            |            |            |            |            |            |            |            |           |            |
|--------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|-----------|------------|
| Byte #       | 15         | 14         | 13         | 12         | 11         | 10         | 9          | 8          | 7          | 6          | 5          | 4          | 3          | 2          | 1         | 0          |
| Bit Position | <b>127</b> | <b>119</b> | <b>111</b> | <b>103</b> | <b>95</b>  | <b>87</b>  | <b>79</b>  | <b>71</b>  | <b>63</b>  | <b>55</b>  | <b>47</b>  | <b>39</b>  | <b>31</b>  | <b>23</b>  | <b>15</b> | <b>7 -</b> |
|              | <b>-</b>   | <b>-</b>   | <b>-</b>   | <b>-</b>   | <b>-88</b> | <b>-80</b> | <b>-72</b> | <b>-64</b> | <b>-56</b> | <b>-48</b> | <b>-40</b> | <b>-32</b> | <b>-24</b> | <b>-16</b> | <b>-8</b> | <b>0</b>   |
|              | 127 - 96   |            |            |            | 95 - 64    |            |            |            | 64 - 32    |            |            |            | 31 - 0     |            |           |            |
| State Word   | X3         |            |            |            | X2         |            |            |            | X1         |            |            |            | X0         |            |           |            |
| State Byte   | P          | O          | N          | M          | L          | K          | J          | I          | H          | G          | F          | E          | D          | C          | B         | A          |

Table 5-2. Matrix Representation of a 128-bit State

|   |   |   |   |         |         |         |         |
|---|---|---|---|---------|---------|---------|---------|
| A | E | I | M | S(0, 0) | S(0, 1) | S(0, 2) | S(0, 3) |
| B | F | J | N | S(1, 0) | S(1, 1) | S(1, 2) | S(1, 3) |
| C | G | K | O | S(2, 0) | S(2, 1) | S(2, 2) | S(2, 3) |
| D | H | L | P | S(3, 0) | S(3, 1) | S(3, 2) | S(3, 3) |

Example:

FIPS vector: d4 bf 5d 30 e0 b4 52 ae b8 41 11 f1 1e 27 98 e5

This vector has the “least significant” byte d4 and the significant byte e5 (written in Big Endian format in the FIPS document). When it is translated to IA notations, the encoding is:

## 5.2.2 AES Transformations and Functions

The following functions and transformations are used in the algorithmic descriptions of AES instruction extensions AESDEC, AESDECLAST, AESENC, AESENCLAST, AESIMC, AESKEYGENASSIST.

Note that these transformations are expressed here in a Little Endian format (and not as in the FIPS 197 document).

- **MixColumns():** A byte-oriented 4x4 matrix transformation on the matrix representation of a 128-bit AES state. A FIPS-197 defined 4x4 matrix is multiplied to each 4x1 column vector of the AES state. The columns are considered polynomials with coefficients in the Finite Field that is used in the definition of FIPS 197, the operations (“multiplication” and “addition”) are in that Finite Field, and the polynomials are reduced modulo  $x^4+1$ .

The MixColumns() transformation defines the relationship between each byte of the result state, represented as  $S'(i, j)$  of a 4x4 matrix (see Section 5.2.1), as a function of input state bytes,  $S(i, j)$ , as follows

$$S'(0, j) \leftarrow \text{FF\_MUL}(02\text{H}, S(0, j)) \text{ XOR } \text{FF\_MUL}(03\text{H}, S(1, j)) \text{ XOR } S(2, j) \text{ XOR } S(3, j)$$

$$S'(1, j) \leftarrow S(0, j) \text{ XOR } \text{FF\_MUL}(02\text{H}, S(1, j)) \text{ XOR } \text{FF\_MUL}(03\text{H}, S(2, j)) \text{ XOR } S(3, j)$$

$$S'(2, j) \leftarrow S(0, j) \text{ XOR } S(1, j) \text{ XOR } \text{FF\_MUL}(02\text{H}, S(2, j)) \text{ XOR } \text{FF\_MUL}(03\text{H}, S(3, j))$$

$$S'(3, j) \leftarrow \text{FF\_MUL}(03\text{H}, S(0, j)) \text{ XOR } S(1, j) \text{ XOR } S(2, j) \text{ XOR } \text{FF\_MUL}(02\text{H}, S(3, j))$$

where  $j = 0, 1, 2, 3$ .  $\text{FF\_MUL}(\text{Byte1}, \text{Byte2})$  denotes the result of multiplying two elements (represented by  $\text{Byte1}$  and  $\text{Byte2}$ ) in the Finite Field representation that defines AES. The result of produced by  $\text{FF\_MUL}(\text{Byte1}, \text{Byte2})$  is an element in the Finite Field (represented as a byte). A Finite Field is a field with a finite number of elements, and when this number can be represented as a power of 2 ( $2^n$ ), its elements can be represented as the set of  $2n$  binary strings of length  $n$ . AES uses a finite field with  $n=8$  (having 256 elements). With this representation, “addition” of two elements in that field is a bit-wise XOR of their binary-string representation, producing another element in the field. Multiplication of two elements in that field is defined using an irreducible polynomial (for AES, this polynomial is  $m(x) = x^8 + x^4 + x^3 + x + 1$ ). In this Finite Field representation, the bit value of bit position  $k$  of a byte represents the coefficient of a polynomial of order  $k$ , e.g., 1010\_1101B (ADH) is represented by the polynomial  $(x^7 + x^5 + x^3 + x^2 + 1)$ . The byte value result of multiplication of two elements is obtained by a carry-less multiplication of the two corresponding polynomials, followed by reduction modulo the polynomial, where the remainder is calculated using operations defined in the field. For example,  $\text{FF\_MUL}(57\text{H}, 83\text{H}) = \text{C1H}$ , because the carry-less polynomial multiplication of the polynomials represented by 57H and 83H produces  $(x^{13} + x^{11} + x^9 + x^8 + x^6 + x^5 + x^4 + x^3 + 1)$ , and the remainder modulo  $m(x)$  is  $(x^7 + x^6 + 1)$ .

- RotWord():** performs a byte-wise cyclic permutation (rotate right in little-endian byte order) on a 32-bit AES word.

The output word  $X'[j]$  of  $\text{RotWord}(X[j])$  where  $X[j]$  represent the four bytes of column  $j$ ,  $S(i, j)$ , in descending order  $X[j] = ( S(3, j), S(2, j), S(1, j), S(0, j) )$ ;  $X'[j] = ( S'(3, j), S'(2, j), S'(1, j), S'(0, j) ) \leftarrow ( S(0, j), S(3, j), S(2, j), S(1, j) )$
- ShiftRows():** A byte-oriented matrix transformation that processes the matrix representation of a 16-byte AES state by cyclically shifting the last three rows of the state by different offset to the left, see Figure 5-5.

Table 5-5. The ShiftRows Transformation

| Matrix Representation of Input State |   |   |   | Output of ShiftRows |   |   |   |
|--------------------------------------|---|---|---|---------------------|---|---|---|
| A                                    | E | I | M | A                   | E | I | M |
| B                                    | F | J | N | F                   | J | N | B |
| C                                    | G | K | O | K                   | O | C | G |
| D                                    | H | L | P | P                   | D | H | L |

- SubBytes():** A byte-oriented transformation that processes the 128-bit AES state by applying a non-linear substitution table (S-BOX) on each byte of the state.

The  $\text{SubBytes}()$  function defines the relationship between each byte of the result state  $S'(i, j)$  as a function of input state byte  $S(i, j)$ , by

$$S'(i, j) \leftarrow \text{S-Box} (S(i, j)[7:4], S(i, j)[3:0])$$

where  $\text{S-BOX}( S[7:4], S[3:0])$  represents a look-up operation on a 16x16 table to return a byte value, see Table 5-6.

Table 5-6. Look-up Table Associated with S-Box Transformation

|        |   | S[3:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------|---|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|        |   | 0      | 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | a  | b  | c  | d  | e  | f  |

- SubWord(): produces an output AES word (four bytes) from the four bytes of an input word using a non-linear substitution table (S-BOX).

$$X'[j] = ( S'(3, j), S'(2, j), S'(1, j), S'(0, j) ) \leftarrow ( S\text{-Box}( S(3, j) ), S\text{-Box}( S(2, j) ), S\text{-Box}( S(1, j) ), S\text{-Box}( S(0, j) ) )$$

- InvMixColumns(): The inverse transformation of MixColumns().

The InvMixColumns() transformation defines the relationship between each byte of the result state  $S'(i, j)$  as a function of input state bytes,  $S(i, j)$ , by

$$S'(0, j) \leftarrow FF\_MUL( 0eH, S(0, j) ) \text{ XOR } FF\_MUL(0bH, S(1, j) ) \text{ XOR } FF\_MUL(0dH, S(2, j) ) \text{ XOR } FF\_MUL( 09H, S(3, j) )$$

$$S'(1, j) \leftarrow FF\_MUL(09H, S(0, j) ) \text{ XOR } FF\_MUL( 0eH, S(1, j) ) \text{ XOR } FF\_MUL(0bH, S(2, j) ) \text{ XOR } FF\_MUL( 0dH, S(3, j) )$$

$$S'(2, j) \leftarrow FF\_MUL(0dH, S(0, j) ) \text{ XOR } FF\_MUL( 09H, S(1, j) ) \text{ XOR } FF\_MUL( 0eH, S(2, j) ) \text{ XOR } FF\_MUL(0bH, S(3, j) )$$

$S'(3, j) \leftarrow \text{FF\_MUL}(0bH, S(0, j)) \text{ XOR } \text{FF\_MUL}(0dH, S(1, j)) \text{ XOR } \text{FF\_MUL}(09H, S(2, j)) \text{ XOR } \text{FF\_MUL}(0eH, S(3, j))$ , where  $j = 0, 1, 2, 3$ .

- **InvShiftRows():** The inverse transformation of ShiftRows(). The InvShiftRows() transforms the matrix representation of a 16-byte AES state by cyclically shifting the last three rows of the state by different offset to the right, see Table 5-7.

Table 5-7. The InvShiftRows Transformation

| Matrix Representation of Input State |   |   |   | Output of ShiftRows |   |   |   |
|--------------------------------------|---|---|---|---------------------|---|---|---|
| A                                    | E | I | M | A                   | E | I | M |
| B                                    | F | J | N | N                   | B | F | J |
| C                                    | G | K | O | K                   | O | C | G |
| D                                    | H | L | P | H                   | L | P | D |

- **InvSubBytes():** The inverse transformation of SubBytes().  
 The InvSubBytes() transformation defines the relationship between each byte of the result state  $S'(i, j)$  as a function of input state byte  $S(i, j)$ , by  
 $S'(i, j) \leftarrow \text{InvS-Box}(S(i, j)[7:4], S(i, j)[3:0])$   
 where  $\text{InvS-BOX}(S[7:4], S[3:0])$  represents a look-up operation on a 16x16 table to return a byte value, see Table 5-8.

Table 5-8. Look-up Table Associated with InvS-Box Transformation

## 5.3 SUMMARY OF TERMS

- **“Legacy SSE”**: Refers to SSE, SSE2, SSE3, SSSE3, SSE4, and any future instruction sets referencing XMM registers and encoded without a VEX prefix.
- **XGETBV, XSETBV, XSAVE, XRSTOR** are defined in *IA-32 Intel Architecture Software Developer’s Manual, Volumes 3A* and *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*.
- **VEX**: refers to a two-byte or three-byte prefix. AVX and FMA instructions are encoded using a VEX prefix.
- **VEX.vvvv**. The VEX bitfield specifying a source or destination register (in 1’s complement form).
- **rm\_field**: shorthand for the ModR/M *r/m* field and any REX.B
- **reg\_field**: shorthand for the ModR/M *reg* field and any REX.R

- VLMAX:** the maximum vector register width pertaining to the instruction. This is not the vector-length encoding in the instruction's prefix but is instead determined by the current value of XCR0. For existing processors, VLMAX is 256 whenever XFEATURE\_ENABLED\_MASK.YMM[bit 2] is 1. Future processors may define new bits in XFEATURE\_ENABLED\_MASK whose setting may imply other values for VLMAX.

**VLMAX Definition**

|                                 |       |
|---------------------------------|-------|
| XFEATURE_ENABLED_MASK Component | VLMAX |
| XFEATURE_ENABLED_MASK.YMM       | 256   |

## 5.4 INSTRUCTION SET REFERENCE

<only instructions modified by AVX are included>

## ADDPD - Add Packed Double Precision Floating-Point Values

| Opcode/<br>Instruction  | Op<br>En | 64/32 bit<br>Mode<br>Support | CPUID<br>Feature<br>Flag | Description   |

### Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Performs a SIMD add of the two or four packed double-precision floating-point values from the first Source operand to the Second Source operand, and stores the packed double-precision floating-point results in the destination operand.

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Adds the low double-precision floating-point values from the second source operand and the first source operand and stores the double-precision floating-point result in the destination operand.

The second source operand can be an XMM register or a 64-bit memory location. The first source and destination operands are XMM registers.

128-bit Legacy SSE version: Bits (VLMAX-1:64) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (127:64) of the XMM register destination are copied from corresponding bits in the first source operand. Bits (VLMAX-1:128) of the destination YMM register are zeroed.

### Operation

#### VADDSD (VEX.128 encoded version)

$$\text{DEST}[63:0] \leftarrow \text{SRC1}[63:0] + \text{SRC2}[63:0]$$

### Description

Adds the low single-precision floating-point values from the second source operand and the first source operand, and stores the double-precision floating-point result in the destination operand.

The second source operand can be an XMM register or a 64-bit memory location. The first source and destination operands are XMM registers.

128-bit Legacy SSE version: Bits (VLMAX-1:32) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (127:32) of the XMM register destination are copied from corresponding bits in the first source operand. Bits (VLMAX-1:128) of the destination YMM register are zeroed.

### Operation

**VADDSS DEST, SRC1, SRC2 (VEX.128 encoded version)**

$DEST[31:0] \leftarrow SRC1[31:0] + SRC2[31:0]$

$DEST[127:32] \leftarrow SRC1[127:32]$

$DEST[VLMAX-1:128] \leftarrow 0$

**ADDSS DEST, SRC (128-bit Legacy SSE version)**

## INSTRUCTION SET REFERENCE

| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Adds odd-numbered double-precision floating-point values of the first source operand (second operand) with the corresponding double-precision floating-point values from the second source operand (third operand); stores the result in the odd-numbered values of the destination operand (first operand). Subtracts the even-numbered double-precision floating-point values from the second source operand from the corresponding double-precision floating values in the first source operand; stores the result into the even-numbered values of the destination operand

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

## AESIMC- Perform the AES InvMixColumn Transformation

| Opcode/<br>Instruction                                  | Op<br>En | 64/32 bit<br>Mode<br>Support | CPUID<br>Feature<br>Flag           | Description  |
|---|----------|------------------------------|------------------------------------|--|
| 66 0F 38 DB /r<br>AESIMC xmm1, xmm2/m128                | A        | V/V                          | AES                                | Perform the InvMixColumn transformation on a 128-bit round key from xmm2/m128 and store the result in xmm1 |
| VEX.128.66.0F38.WIG DB /r<br>VAESIMC xmm1,<br>xmm2/m128 | A        | V/V                          | Both<br>AES<br>and<br>AVX<br>flags | Perform the InvMixColumn transformation on a 128-bit round key from xmm2/m128 and store the result in xmm1 |

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

### Description

Perform the InvMixColumns transformation on the source operand and store the result in the destination operand. The destination operand is an XMM register. The source operand can be an XMM register or a 128-bit memory location.

Note the AESIMC instruction should be applied to the expanded AES round keys (except for the first and last round key) in order to prepare them for decryption using the “Equivalent Inverse Cipher” (defined in FIPS 197).

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

### Operation

#### VAESIMC

```
DEST[127:0] ← InvMixColumns( SRC );
DEST[VLMAX-1:128] ← 0;
```

#### AESIMC

```
DEST[127:0] ← InvMixColumns( SRC );
DEST[VLMAX-1:128] (Unmodified)
```

## Description

Assist in expanding the AES cipher key, by computing steps towards generating a round key for encryption, using 128-bit data specified in the source operand and an 8-bit round constant specified as an immediate, store the result in the destination operand.

The destination operand is an XMM register. The source operand can be an XMM register or a 128-bit memory location.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

## Operation

**VAESKEYGENASSIST**

X3[31:0] ← SRC [127: 96];

X2[31:0] ← SRC [95: 64];

### Description

Double-precision floating-point values from the second source operand (third operand) are conditionally merged with values from the first source operand (second operand) and written to the destination operand (first operand). The immediate bits [3:0] determine whether the corresponding double-precision floating-point value in the destination is copied from the second source or first source. If a bit in the mask, corresponding to a word, is "1", then the double-precision floating-point value in the second source operand is copied, else the value in the first source operand is copied.

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register. The second source operand is an XMM register or 128-bit memory location. The destination

operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

## Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4  |
|---|------------------|---------------|---------------|-----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA        |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | imm8[7:4] |

## Description

Conditionally copy each quadword data element of double-precision floating-point value from the second source operand and the first source operand depending on mask bits defined in the mask register operand. The mask bits are the most significant bit in each quadword element of the mask register.

Each quadword element of the destination operand is copied from:

- the corresponding quadword element in the second source operand, If a mask bit is "1"; or
- the corresponding quadword element in the first source operand, If a mask bit is "0"

The register assignment of the implicit mask operand for BLENDVPD is defined to be the architectural register XMM0.

128-bit Legacy SSE version: The first source operand and the destination operand is the same. Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged. The mask register operand is implicitly defined to be the architectural register XMM0. An attempt to execute BLENDVPD with a VEX prefix will cause #UD.

VEX.128 encoded version: The first source operand and the destination operand are XMM registers. The second source operand is an XMM register or 128-bit memory location. The mask operand is the third source register, and encoded in bits[7:4] of the immediate byte(imm8). The bits[3:0] of imm8 are ignored. In 32-bit mode, imm8[7] is ignored. The upper bits (VLMAX-1:128) of the corresponding YMM register (destination register) are zeroed. VEX.W must be 0, otherwise, the instruction will #UD.

VEX.256 encoded version: The first source operand and destination operand are YMM registers. The second source operand can be a YMM register or a 256-bit memory location. The mask operand is the third source register, and encoded in bits[7:4] of the immediate byte(imm8). The bits[3:0] of imm8 are ignored. In 32-bit mode, imm8[7] is ignored. VEX.W must be 0, otherwise, the instruction will #UD.

VBLENDVPD permits the mask to be any XMM or YMM register. In contrast, BLENDVPD treats XMM0 implicitly as the mask and do not support non-destructive destination operation.

### Description

Conditionally copy each dword data element of single-precision floating-point value from the second source operand and the first source operand depending on mask bits defined in the mask register operand. The mask bits are the most significant bit in each dword element of the mask register.

Each quadword element of the destination operand is copied from:

- the corresponding dword element in the second source operand, If a mask bit is "1"; or
- the corresponding dword element in the first source operand, If a mask bit is "0"

The register assignment of the implicit mask operand for BLENDVPS is defined to be the architectural register XMM0.

128-bit Legacy SSE version: The first source operand and the destination operand is the same. Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged. The mask register operand is implicitly defined to be the architectural register XMM0. An attempt to execute BLENDVPS with a VEX prefix will cause #UD.

VEX.128 encoded version: The first source operand and the destination operand are XMM registers. The second source operand is an XMM register or 128-bit memory location. The mask operand is the third source register, and encoded in bits[7:4] of the immediate byte(imm8). The bits[3:0] of imm8 are ignored. In 32-bit mode, imm8[7] is ignored. The upper bits (VLMAX-1:128) of the corresponding YMM register (destination register) are zeroed. VEX.W must be 0, otherwise, the instruction will #UD.

VEX.256 encoded version: The first source operand and destination operand are YMM registers. The second source operand can be a YMM register or a 256-bit memory location. The mask operand is the third source register, and encoded in bits[7:4] of the immediate byte(imm8). The bits[3:0] of imm8 are ignored. In 32-bit mode, imm8[7] is ignored. VEX.W must be 0, otherwise, the instruction will #UD.

VBLENDVPS permits the mask to be any XMM or YMM register. In contrast, BLENDVPS treats XMM0 implicitly as the mask and do not support non-destructive destination operation.

## Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

## Description

Load floating point values from the source operand (second operand) and broadcast to all elements of the destination operand (first operand).

The destination operand is a YMM register. The source operand is either a 32-bit, 64-bit, or 128-bit memory location. Register source encodings are reserved and will #UD.

VBROADCASTSD and VBROADCASTF128 are only supported as 256-bit wide versions. VBROADCASTSS is supported in both 128-bit and 256-bit wide versions.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

If VBROADCASTSD or VBROADCASTF128 is encoded with VEX.L= 0, an attempt to execute the instruction encoded with VEX.L= 0 will cause an #UD exception.

### Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Performs a SIMD compare of the packed double-precision floating-point values in the second source operand and the first source operand and returns the results of the comparison to the destination operand. The comparison predicate operand (immediate byte) specifies the type of comparison performed on each pair of packed values in the two source operands. The result of each comparison is a quadword mask of all 1s (comparison true) or all 0s (comparison false).

VEX.256 encoded version: The first source operand (second operand) is a YMM register. The second source operand (third operand) can be a YMM register or a 256-bit memory location. The destination operand (first operand) is a YMM register. Four comparisons are performed with results written to the destination operand.

128-bit Legacy SSE version: The first source and destination operand (first operand) is an XMM register. The second source operand (second operand) can be an XMM

register or 128-bit memory location. Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged. Two comparisons are performed with results written to bits 127:0 of the destination operand.

VEX.128 encoded version: The first source operand (second operand) is an XMM register. The second source operand (third operand) can be an XMM register or a 128-bit memory location. Bits (VLMAX-1:128) of the destination YMM register are zeroed. Two comparisons are performed with results written to bits 127:0 of the destination operand.

The comparison predicate operand is an 8-bit immediate:

- For instructions encoded using the VEX prefix, bits 4:0 define the type of comparison to be performed (see Table 5-9). Bits 5 through 7 of the immediate are reserved.
- For instruction encodings that do not use VEX prefix, bits 2:0 define the type of comparison to be made (see the first 8 rows of Table 5-9). Bits 3 through 7 of the immediate are reserved.

**NOTES:**

1. If either operand A or B is a NaN.

The unordered relationship is true when at least one of the two source operands being compared is a NaN; the ordered relationship is true when neither source operand is a NaN.

A subsequent computational instruction that uses the mask result in the destination operand as an input operand will not generate an exception, because a mask of all 0s corresponds to a floating-point value of +0.0 and a mask of all 1s corresponds to a QNaN.

Note that processors with "CPUID.1H:ECX.AVX = 0" do not implement the "greater-than", "greater-than-or-equal", "not-greater than", and "not-greater-than-or-equal relations" predicates. These comparisons can be made either by using the inverse relationship (that is, use the "not-less-than-or-equal" to make a "greater-than" comparison) or by using software emulation. When using software emulation, the

program must swap the operands (copying registers when necessary to protect the data that will now be in the destination), and then perform the compare using a different predicate. The predicate to be used for these emulations is listed in the first 8 rows of Table 3-7 (*Intel 64 and IA-32 Architectures Software Developer's Manual Volume 2A*) under the heading Emulation.

Compilers and assemblers may implement the following two-operand pseudo-ops in addition to the three-operand CMPPD instruction, for processors with "CPUID.1H:ECX.AVX =0". See Table 5-10. Compiler should treat reserved Imm8 values as illegal syntax.

Table 5-10. Pseudo-Op and CMPPD Implementation

| Pseudo-Op                    | CMPPD Implementation       |
|------------------------------|----------------------------|
| CMPEQPD <i>xmm1, xmm2</i>    | CMPPD <i>xmm1, xmm2, 0</i> |
| CMPLTPD <i>xmm1, xmm2</i>    | CMPPD <i>xmm1, xmm2, 1</i> |

The greater-than relations that the processor does not implement require more than one instruction to emulate in software and therefore should not be implemented as pseudo-ops. (For these, the programmer should reverse the operands of the corresponding less than relations and use move instructions to ensure that the mask is moved to the correct destination register and that the source operand is left intact.)

Processors with "CPUID.1H:ECX.AVX =1" implement the full complement of 32 predicates shown in Table 5-9, software emulation is no longer needed. Compilers and assemblers may implement the following three-operand pseudo-ops in addition to the four-operand VCMPPD instruction. See Table 5-11, where the notations of *reg1*, *reg2*, and *reg3* represent either XMM registers or YMM registers. Compiler should treat reserved Imm8 values as illegal syntax. Alternately, intrinsics can map the pseudo-ops to pre-defined constants to support a simpler intrinsic interface.

| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Performs a SIMD compare of the packed single-precision floating-point values in the second source operand and the first source operand and returns the results of the comparison to the destination operand. The comparison predicate operand (immediate byte) specifies the type of comparison performed on each of the pairs of packed values. The result of each comparison is a quadword mask of all 1s (comparison true) or all 0s (comparison false).

VEX.256 encoded version: The first source operand (second operand) is a YMM register. The second source operand (third operand) can be a YMM register or a 256-bit memory location. The destination operand (first operand) is a YMM register. Eight comparisons are performed with results written to the destination operand.

128-bit Legacy SSE version: The first source and destination operand (first operand) is an XMM register. The second source operand (second operand) can be an XMM

register or 128-bit memory location. Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged. Four comparisons are performed with results written to bits 127:0 of the destination operand.

VEX.128 encoded version: The first source operand (second operand) is an XMM register. The second source operand (third operand) can be an XMM register or a 128-bit memory location. Bits (VLMAX-1:128) of the destination YMM register are zeroed. Four comparisons are performed with results written to bits 127:0 of the destination operand.

The comparison predicate operand is an 8-bit immediate:

- For instructions encoded using the VEX prefix, bits 4:0 define the type of comparison to be performed (see Figure 5-9). Bits 5 through 7 of the immediate are reserved.
- For instruction encodings that do not use VEX prefix, bits 2:0 define the type of comparison to be made (see the first 8 rows of Table 5-9). Bits 3 through 7 of the immediate are reserved.

The unordered relationship is true when at least one of the two source operands being compared is a NaN; the ordered relationship is true when neither source operand is a NaN.

A subsequent computational instruction that uses the mask result in the destination operand as an input operand will not generate an exception, because a mask of all 0s corresponds to a floating-point value of +0.0 and a mask of all 1s corresponds to a QNaN.

Note that processors with "CPUID.1H:ECX.AVX =0" do not implement the "greater-than", "greater-than-or-equal", "not-greater than", and "not-greater-than-or-equal relations" predicates. These comparisons can be made either by using the inverse relationship (that is, use the "not-less-than-or-equal" to make a "greater-than" comparison) or by using software emulation. When using software emulation, the program must swap the operands (copying registers when necessary to protect the data that will now be in the destination), and then perform the compare using a different predicate. The predicate to be used for these emulations is listed in the first 8 rows of Table 3-7 (*Intel 64 and IA-32 Architectures Software Developer's Manual Volume 2A*) under the heading Emulation.

Compilers and assemblers may implement the following two-operand pseudo-ops in addition to the three-operand CMPPS instruction, for processors with "CPUID.1H:ECX.AVX =0". See Table 5-12. Compiler should treat reserved Imm8 values as illegal syntax.

Table 5-12. Pseudo-Op and CMPPS Implementation

### Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Compares the low double-precision floating-point values in the second source operand and the first source operand and returns the results in of the comparison to the destination operand. The comparison predicate operand (immediate operand) specifies the type of comparison performed. The comparison result is a quadword mask of all 1s (comparison true) or all 0s (comparison false).

128-bit Legacy SSE version: The first source and destination operand (first operand) is an XMM register. The second source operand (second operand) can be an XMM register or 64-bit memory location. Bits (VLMAX-1:64) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: The first source operand (second operand) is an XMM register. The second source operand (third operand) can be an XMM register or a 64-bit memory location. The result is stored in the low quadword of the destination operand; the high quadword is filled with the contents of the high quadword of the first source operand. Bits (VLMAX-1:128) of the destination YMM register are zeroed.

The comparison predicate operand is an 8-bit immediate:

- For instructions encoded using the VEX prefix, bits 4:0 define the type of comparison to be performed (see Table 5-9). Bits 5 through 7 of the immediate are reserved.

- For instruction encodings that do not use VEX prefix, bits 2:0 define the type of comparison to be made (see the first 8 rows of Table 5-9). Bits 3 through 7 of the immediate are reserved.

The unordered relationship is true when at least one of the two source operands being compared is a NaN; the ordered relationship is true when neither source operand is a NaN.

A subsequent computational instruction that uses the mask result in the destination operand as an input operand will not generate an exception, because a mask of all 0s corresponds to a floating-point value of +0.0 and a mask of all 1s corresponds to a QNaN.

Note that processors with "CPUID.1H:ECX.AVX = 0" do not implement the "greater-than", "greater-than-or-equal", "not-greater than", and "not-greater-than-or-equal relations" predicates. These comparisons can be made either by using the inverse relationship (that is, use the "not-less-than-or-equal" to make a "greater-than" comparison) or by using software emulation. When using software emulation, the program must swap the operands (copying registers when necessary to protect the data that will now be in the destination), and then perform the compare using a different predicate. The predicate to be used for these emulations is listed in the first 8 rows of Table 3-7 (*Intel 64 and IA-32 Architectures Software Developer's Manual Volume 2A*) under the heading Emulation.

Compilers and assemblers may implement the following two-operand pseudo-ops in addition to the three-operand CMPSD instruction, for processors with "CPUID.1H:ECX.AVX = 0". See Table 5-14. Compiler should treat reserved Imm8 values as illegal syntax.

Table 5-14. Pseudo-Op and CMPSD Implementation

| Pseudo-Op                    | CMPSD Implementation       |
|------------------------------|----------------------------|
| CMPEQSD <i>xmm1, xmm2</i>    | CMPSD <i>xmm1, xmm2, 0</i> |
| CMPLTSD <i>xmm1, xmm2</i>    | CMPSD <i>xmm1, xmm2, 1</i> |
| CMPLESD <i>xmm1, xmm2</i>    | CMPSD <i>xmm1, xmm2, 2</i> |
| CMPUNORDSD <i>xmm1, xmm2</i> | CMPSD <i>xmm1, xmm2, 3</i> |
| CMPNEQSD <i>xmm1, xmm2</i>   | CMPSD <i>xmm1, xmm2, 4</i> |
| CMPNLTSD <i>xmm1, xmm2</i>   | CMPSD <i>xmm1, xmm2, 5</i> |
| CMPNLESD <i>xmm1, xmm2</i>   | CMPSD <i>xmm1, xmm2, 6</i> |
| CMPORDSD <i>xmm1, xmm2</i>   | CMPSD <i>xmm1, xmm2, 7</i> |

The greater-than relations that the processor does not implement require more than one instruction to emulate in software and therefore should not be implemented as pseudo-ops. (For these, the programmer should reverse the operands of the corresponding less than relations and use move instructions to ensure that the mask is moved to the correct destination register and that the source operand is left intact.)

Processors with “CPUID.1H:ECX.AVX =1” implement the full complement of 32 predicates shown in Table 5-15, software emulation is no longer needed. Compilers and assemblers may implement the following three-operand pseudo-ops in addition to the four-operand VCMPSD instruction. See Table 5-15, where the notations of reg1 reg2, and reg3 represent either XMM registers or YMM registers. Compiler should treat reserved Imm8 values as illegal syntax. Alternately, intrinsics can map the pseudo-ops to pre-defined constants to support a simpler intrinsic interface.

### Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Compares the low single-precision floating-point values in the second source operand and the first source operand and returns the results of the comparison to the destination operand. The comparison predicate operand (immediate operand) specifies the type of comparison performed. The comparison result is a doubleword mask of all 1s (comparison true) or all 0s (comparison false).

128-bit Legacy SSE version: The first source and destination operand (first operand) is an XMM register. The second source operand (second operand) can be an XMM register or 32-bit memory location. Bits (VLMAX-1:32) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: The first source operand (second operand) is an XMM register. The second source operand (third operand) can be an XMM register or a 32-bit memory location. The result is stored in the low 32 bits of the destination operand; bits 128:32 of the destination operand are copied from the first source operand. Bits (VLMAX-1:128) of the destination YMM register are zeroed.

The comparison predicate operand is an 8-bit immediate:

- For instructions encoded using the VEX prefix, bits 4:0 define the type of comparison to be performed (see Table 5-9). Bits 5 through 7 of the immediate are reserved.

- For instruction encodings that do not use VEX prefix, bits 2:0 define the type of comparison to be made (see the first 8 rows of Table 5-9). Bits 3 through 7 of the immediate are reserved.

The unordered relationship is true when at least one of the two source operands being compared is a NaN; the ordered relationship is true when neither source operand is a NaN.

A subsequent computational instruction that uses the mask result in the destination operand as an input operand will not generate an exception, because a mask of all 0s corresponds to a floating-point value of +0.0 and a mask of all 1s corresponds to a QNaN.

Note that processors with "CPUID.1H:ECX.AVX =0" do not implement the "greater-than", "greater-than-or-equal", "not-greater than", and "not-greater-than-or-equal relations" predicates. These comparisons can be made either by using the inverse relationship (that is, use the "not-less-than-or-equal" to make a "greater-than" comparison) or by using software emulation. When using software emulation, the program must swap the operands (copying registers when necessary to protect the data that will now be in the destination), and then perform the compare using a different predicate. The predicate to be used for these emulations is listed in the first 8 rows of Table 3-7 (*Intel 64 and IA-32 Architectures Software Developer's Manual Volume 2A*) under the heading Emulation.

Compilers and assemblers may implement the following two-operand pseudo-ops in addition to the three-operand CMPSS instruction, for processors with "CPUID.1H:ECX.AVX =0". See Table 5-16. Compiler should treat reserved Imm8 values as illegal syntax.

Table 5-16. Pseudo-Op and CMPSS Implementation

| Pseudo-Op                    | CMPSS Implementation       |
|------------------------------|----------------------------|
| CMPEQSS <i>xmm1, xmm2</i>    | CMPSS <i>xmm1, xmm2, 0</i> |
| CMPLTSS <i>xmm1, xmm2</i>    | CMPSS <i>xmm1, xmm2, 1</i> |
| CMPLESS <i>xmm1, xmm2</i>    | CMPSS <i>xmm1, xmm2, 2</i> |
| CMPUNORDSS <i>xmm1, xmm2</i> | CMPSS <i>xmm1, xmm2, 3</i> |
| CMPNEQSS <i>xmm1, xmm2</i>   | CMPSS <i>xmm1, xmm2, 4</i> |
| CMPNLTSS <i>xmm1, xmm2</i>   | CMPSS <i>xmm1, xmm2, 5</i> |
| CMPNLESS <i>xmm1, xmm2</i>   | CMPSS <i>xmm1, xmm2, 6</i> |
| CMPORDSS <i>xmm1, xmm2</i>   | CMPSS <i>xmm1, xmm2, 7</i> |

The greater-than relations that the processor does not implement require more than one instruction to emulate in software and therefore should not be implemented as pseudo-ops. (For these, the programmer should reverse the operands of the corresponding less than relations and use move instructions to ensure that the mask is moved to the correct destination register and that the source operand is left intact.)

Processors with “CPUID.1H:ECX.AVX =1” implement the full complement of 32 predicates shown in Table 5-15, software emulation is no longer needed. Compilers and assemblers may implement the following three-operand pseudo-ops in addition to the four-operand VCMPS instruction. See Table 5-17, where the notations of reg1, reg2, and reg3 represent either XMM registers or YMM registers. Compiler should treat reserved Imm8 values as illegal syntax. Alternately, intrinsics can map the pseudo-ops to pre-defined constants to support a simpler intrinsic interface.

## COMISD- Compare Scalar Ordered Double-Precision Floating-Point Values and Set EFLAGS

| Opcode/<br>Instruction                               | Op<br>En | 64/32 bit<br>Mode<br>Support | CPUID<br>Feature<br>Flag | Description   |
|--|----------|------------------------------|--------------------------|---|
| 66 0F 2F /r<br>COMISD xmm1, xmm2/m64                 | A        | V/V                          | SSE2                     | Compare low double precision floating-point values in xmm1 and xmm2/mem64 and set the EFLAGS flags accordingly. |
| VEX.LIG.66.0F.WIG 2F /r<br>VCOMISD xmm1,<br>xmm2/m64 | A        | V/V                          | AVX                      | Compare low double precision floating-point values in xmm1 and xmm2/mem64 and set the EFLAGS flags accordingly. |

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

### Description

Compares the double-precision floating-point values in the low quadwords of operand 1 (first operand) and operand 2 (second operand), and sets the ZF, PF, and CF flags in the EFLAGS register according to the result (unordered, greater than, less than, or equal). The OF, SF and AF flags in the EFLAGS register are set to 0. The unordered result is returned if either source operand is a NaN (QNaN or SNaN).

Operand 1 is an XMM register; operand 2 can be an XMM register or a 64 bit memory location. The COMISD instruction differs from the UCOMISD instruction in that it signals a SIMD floating-point invalid operation exception (#I) when a source operand is either a QNaN or SNaN. The UCOMISD instruction signals an invalid numeric exception only if a source operand is an SNaN.

The EFLAGS register is not updated if an unmasked SIMD floating-point exception is generated.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

### Operation

#### COMISD (all versions)

| 0F 2F /r<br>COMISS xmm1, xmm2/m32                        | A        | V/V                          | SSE                      | Compare low single precision floating-point values in xmm1 and xmm2/mem32 and set the EFLAGS flags accordingly. |
| VEX.LIG0F 2F.WIG /r<br><b>VCOMISS xmm1,<br/>xmm2/m32</b> | A        | V/V                          | AVX                      | Compare low single precision floating-point values in xmm1 and xmm2/mem32 and set the EFLAGS flags accordingly. |

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

### Description

Compares the single-precision floating-point values in the low quadwords of operand 1 (first operand) and operand 2 (second operand), and sets the ZF, PF, and CF flags in the EFLAGS register according to the result (unordered, greater than, less than, or equal). The OF, SF and AF flags in the EFLAGS register are set to 0. The unordered result is returned if either source operand is a NaN (QNaN or SNaN).

Operand 1 is an XMM register; operand 2 can be an XMM register or a 32 bit memory location.

The COMISS instruction differs from the UCOMISS instruction in that it signals a SIMD floating-point invalid operation exception (#I) when a source operand is either a QNaN or SNaN. The UCOMISS instruction signals an invalid numeric exception only if a source operand is an SNaN.

The EFLAGS register is not updated if an unmasked SIMD floating-point exception is generated.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

### Description

Converts two or four packed double-precision floating-point values in the source operand (second operand) to two or four packed signed doubleword integers in the destination operand (first operand).

When a conversion is inexact, the value returned is rounded according to the rounding control bits in the MXCSR register. If a converted result is larger than the maximum signed doubleword integer, the floating-point invalid exception is raised, and if this exception is masked, the indefinite integer value (80000000H) is returned

VEX.256 encoded version: The source operand is a YMM register or 256-bit memory location. The destination operation is an XMM register. The upper bits (255:128) of the corresponding YMM register destination are zeroed.

VEX.128 encoded version: The source operand is an XMM register or 128-bit memory location. The destination operation is a YMM register. The upper bits (VLMAX-1:64) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The source operand is an XMM register or 128-bit memory location. The destination operation is an XMM register. Bits[127:64] of the destination XMM register are zeroed. However, the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

### Description

Converts two or four packed double-precision floating-point values in the source operand (second operand) to two or four packed single-precision floating-point values in the destination operand (first operand).

When a conversion is inexact, the value returned is rounded according to the rounding control bits in the MXCSR register.

VEX.256 encoded version: The source operand is a YMM register or 256-bit memory location. The destination operation is an XMM register. The upper bits (255:128) of the corresponding YMM register destination are zeroed.

VEX.128 encoded version: The source operand is an XMM register or 128-bit memory location. The destination operation is a YMM register. The upper bits (VLMAX-1:64) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The source operand is an XMM register or 128-bit memory location. The destination operation is an XMM register. Bits[127:64] of the destination XMM register are zeroed. However, the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

### Description

Converts four or eight packed single-precision floating-point values in the source operand to four or eight signed doubleword integers in the destination operand.

When a conversion is inexact, the value returned is rounded according to the rounding control bits in the MXCSR register. If a converted result is larger than the maximum signed doubleword integer, the floating-point invalid exception is raised, and if this exception is masked, the indefinite integer value (80000000H) is returned.

VEX.256 encoded version: The source operand is a YMM register or 256-bit memory location. The destination operation is a YMM register.

VEX.128 encoded version: The source operand is an XMM register or 128-bit memory location. The destination operation is a YMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The source operand is an XMM register or 128-bit memory location. The destination operation is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

| B | ModRM:reg (w) | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Converts a double-precision floating-point value in the second source operand to a single-precision floating-point value in the destination operand.

When the second source operand is an XMM register, the double-precision floating-point value is contained in the low quadword of the register. The result is stored in the low doubleword of the destination operand, and the upper 3 doublewords are copied from the upper 3 doublewords of the first source operand. When the conversion is inexact, the value returned is rounded according to the rounding control bits in the MXCSR register.

The second source operand can be an XMM register or a 64-bit memory location. The first source and destination operands are XMM registers.

128-bit Legacy SSE version: The destination and first source operand are the same. Bits (VLMAX-1:32) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (127:64) of the XMM register destination are copied from corresponding bits in the first source operand. Bits (VLMAX-1:128) of the destination YMM register are zeroed.

### Description

Converts a signed doubleword integer (or signed quadword integer if operand size is 64 bits) in the second source operand to a double-precision floating-point value in the destination operand. The result is stored in the low quadword of the destination operand, and the high quadword left unchanged. When conversion is inexact, the value returned is rounded according to the rounding control bits in the MXCSR register.

## INSTRUCTION SET REFERENCE

Legacy SSE instructions: Use of the REX.W prefix promotes the instruction to 64-bit operands. See the summary chart at the beginning of this section for encoding data and limits.

The second source operand can be a general-purpose register or a 32/64-bit memory location. The first source and destination operands are XMM registers.

128-bit Legacy SSE version: The destination and first source operand are the same. Bits (VLMAX-1:64) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (127:64) of the XMM register destination are copied from corresponding bits in the first source operand. Bits (VLMAX-1:128) of the destination YMM register are zeroed.

| B | ModRM:reg (w) | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Converts a signed doubleword integer (or signed quadword integer if operand size is 64 bits) in the source operand (second operand) to a single-precision floating-point value in the destination operand (first operand). The source operand can be a general-purpose register or a memory location. The destination operand is an XMM register. The result is stored in the low doubleword of the destination operand, and the upper three doublewords are left unchanged. When a conversion is inexact, the

value returned is rounded according to the rounding control bits in the MXCSR register.

Legacy SSE instructions: In 64-bit mode, Use of the REX.W prefix promotes the instruction to 64-bit operands. See the summary chart at the beginning of this section for encoding data and limits.

The second source operand can be a general-purpose register or a 32/64-bit memory location. The first source and destination operands are XMM registers.

128-bit Legacy SSE version: The destination and first source operand are the same. Bits (VLMAX-1:32) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (127:32) of the XMM register destination are copied from corresponding bits in the first source operand. Bits (VLMAX-1:128) of the destination YMM register are zeroed.

|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

### Description

Converts two or four packed double-precision floating-point values in the source operand (second operand) to two or four packed signed doubleword integers in the destination operand (first operand).

When a conversion is inexact, a truncated (round toward zero) value is returned. If a converted result is larger than the maximum signed doubleword integer, the floating-point invalid exception is raised, and if this exception is masked, the indefinite integer value (80000000H) is returned.

VEX.256 encoded version: The source operand is a YMM register or 256-bit memory location. The destination operation is an XMM register. The upper bits (255:128) of the corresponding YMM register destination are zeroed.

VEX.128 encoded version: The source operand is an XMM register or 128-bit memory location. The destination operation is a YMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The source operand is an XMM register or 128-bit memory location. The destination operation is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

### Description

Converts a double-precision floating-point value in the source operand (second operand) to a signed doubleword integer (or signed quadword integer if operand size is 64 bits) in the destination operand (first operand). The source operand can be an XMM register or a 64-bit memory location. The destination operand is a general purpose register. When the source operand is an XMM register, the double-precision floating-point value is contained in the low quadword of the register.

When a conversion is inexact, a truncated (round toward zero) result is returned. If a converted result is larger than the maximum signed doubleword integer, the floating point invalid exception is raised. If this exception is masked, the indefinite integer value (80000000H) is returned.

Legacy SSE instructions: In 64-bit mode, Use of the REX.W prefix promotes the instruction to 64-bit operation. See the summary chart at the beginning of this section for encoding data and limits.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

| VEX.LIG.F3.0F.W1 2C /r<br>VCVTTSS2SI r64,<br>xmm1/m32 | A        | V/N.E.                       | AVX                      | Convert one single-precision floating-point value from xmm1/m32 to one signed quadword integer in r64 using truncation.   |

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

### Description

Converts a single-precision floating-point value in the source operand (second operand) to a signed doubleword integer (or signed quadword integer if operand size is 64 bits) in the destination operand (first operand). The source operand can be an XMM register or a 32-bit memory location. The destination operand is a general purpose register. When the source operand is an XMM register, the single-precision floating-point value is contained in the low doubleword of the register.

When a conversion is inexact, a truncated (round toward zero) result is returned. If a converted result is larger than the maximum signed doubleword integer, the floating point invalid exception is raised. If this exception is masked, the indefinite integer value (80000000H) is returned.

Legacy SSE instructions: In 64-bit mode, Use of the REX.W prefix promotes the instruction to 64-bit operation. See the summary chart at the beginning of this section for encoding data and limits.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

### Operation

#### **CVTTSS2SI**

IF 64-Bit Mode and OperandSize = 64

THEN

DEST[63:0] ← Convert\_Single\_Precision\_Floating\_Point\_To\_Integer\_Truncate(SRC[31:0]);

ELSE

DEST[31:0] ← Convert\_Single\_Precision\_Floating\_Point\_To\_Integer\_Truncate(SRC[31:0]);

| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Performs a SIMD divide of the two or four packed double-precision floating-point values in the first source operand by the two or four packed double-precision floating-point values in the second source operand.

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Divides the low double-precision floating-point value in the first source operand by the low double-precision floating-point value in the second source operand, and stores the double-precision floating-point result in the destination operand. The second source operand can be an XMM register or a 64-bit memory location. The first source and destination hyperons are XMM registers. The high quadword of the destination operand is copied from the high quadword of the first source operand. See Chapter 11 in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1, for an overview of a scalar double-precision floating-point operation.

128-bit Legacy SSE version: The first source operand and the destination operand are the same. Bits (VLMAX-1:64) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed.

### Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Conditionally multiplies the packed double precision floating-point values in the destination operand (first operand) with the packed double-precision floating-point values in the source (second operand) depending on a mask extracted from bits 4-5 of the immediate operand. Each of the two resulting double-precision values is summed and this sum is conditionally broadcast to each of 2 positions in the destination operand if the corresponding bit of the mask selected from bits 0-1 of the immediate operand is "1". If the corresponding low bit 0-1 of the mask is zero, the destination is set to zero. DPPD follows the NaN forwarding rules stated in the Software Developer's Manual, vol. 1, table 4.7. These rules do not cover horizontal prioritization of NaNs. Horizontal propagation of NaNs to the destination and the positioning of those NaNs in the destination is implementation dependent. NaNs on the input sources or computationally generated NaNs will have at least one NaN propagated to the destination.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

If VDPDP is encoded with VEX.L= 1, an attempt to execute the instruction encoded with VEX.L= 1 will cause an #UD exception.

### Operation

#### DP\_primitive (SRC1, SRC2)

```
IF (imm8[4] == 1) THEN Temp1[63:0] ← SRC1[63:0] * SRC2[63:0];
ELSE Temp1[63:0] ← +0.0;
IF (imm8[5] == 1) THEN Temp1[127:64] ← SRC1[127:64] * SRC2[127:64];
ELSE Temp1[127:64] ← +0.0;
Temp2[63:0] ← Temp1[63:0] + Temp1[127:64];
IF (imm8[0] == 1) THEN DEST[63:0] ← Temp2[63:0];
ELSE DEST[63:0] ← +0.0;
IF (imm8[1] == 1) THEN DEST[127:64] ← Temp2[63:0];
ELSE DEST[127:64] ← +0.0;
```

#### VDPPD (VEX.128 encoded version)

```
DEST[127:0] ← DP_Primitive(SRC1[127:0], SRC2[127:0]);
DEST[VLMAX-1:128] ← 0
```

#### DPPD (128-bit Legacy SSE version)

```
DEST[127:0] ← DP_Primitive(SRC1[127:0], SRC2[127:0]);
DEST[VLMAX-1:128] (Unmodified)
```

### Intel C/C++ Compiler Intrinsic Equivalent

```
DPPD __m128d _mm_dp_pd ( __m128d a, __m128d b, const int mask);
```

### SIMD Floating-Point Exceptions

Overflow, Underflow, Invalid, Precision, Denormal

Exceptions are determined separately for each add and multiply operation. Unmasked exceptions will leave the destination untouched

### Other Exceptions

See Exceptions Type 2; additionally

```
#UD                If VEX.L=1
```

### Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Multiplies the packed single precision floating point values in the first source operand (second operand) with the packed single-precision floats in the second source (third operand). Each of the four resulting single-precision values is conditionally summed depending on a mask extracted from the high 4 bits of the immediate operand. This sum is broadcast to each of 4 positions in the destination operand (first operand) if the corresponding bit of the mask selected from the low 4 bits of the immediate operand is "1". If the corresponding low bit 0-3 of the mask is zero, the destination is set to zero.

The process is replicated for the high elements of the destination YMM.

DPPS follows the NaN forwarding rules stated in the Software Developer's Manual, vol. 1, table 4.7. These rules do not cover horizontal prioritization of NaNs. Horizontal

propagation of NaNs to the destination and the positioning of those NaNs in the destination is implementation dependent. NaNs on the input sources or computationally generated NaNs will have at least one NaN propagated to the destination.

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

## Operation

### DP\_primitive (SRC1, SRC2)

IF (imm8[4] == 1) THEN Temp1[31:0] ← SRC1[31:0] \* SRC2[31:0];  
ELSE Temp1[31:0] ← +0.0;

**SIMD Floating-Point Exceptions**

Overflow, Underflow, Invalid, Precision, Denormal

Exceptions are determined separately for each add and multiply operation, in the order of their execution. Unmasked exceptions will leave the destination operands unchanged.

**Other Exceptions**

See Exceptions Type 2

## VEEXTRACTF128- Extract packed floating-point values

| Opcode/<br>Instruction  | Op<br>En | 64/32 bit<br>Mode<br>Support | CPUID<br>Feature<br>Flag | Description  |
|---|----------|------------------------------|--------------------------|--|
| VEX.256.66.0F3A.W0 19 /r ib<br>VEEXTRACTF128<br>xmm1/m128, ymm2, imm8 | A        | V/V                          | AVX                      | Extract 128 bits of packed floating-point values from ymm2 and store results in xmm1/mem |

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:r/m (w) | ModRM:reg (r) | NA       | NA       |

### Description

Extracts 128-bits of packed floating-point values from the source operand (second operand) at a 128-bit offset from imm8[0] into the destination operand (first operand). The destination may be either an XMM register or a 128-bit memory location.

VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

The high 7 bits of the immediate are ignored.

If VEEXTRACTF128 is encoded with VEX.L= 0, an attempt to execute the instruction encoded with VEX.L= 0 will cause an #UD exception.

### Operation

#### VEEXTRACTF128 (memory destination form)

CASE (imm8[0]) OF

0: DEST[127:0] ← SRC1[127:0]

|--|----------|------------------------------|--------------------------|---|
| 66 0F 3A 17 /r ib<br>EXTRACTPS reg/m32,<br>xmm1, imm8              | A        | VV                           | SSE4_1                   | Extract one single-precision floating-point value from xmm1 at the offset specified by imm8 and store the result in reg or m32. Zero extend the results in 64-bit register if applicable. |
| VEX.128.66.0F3A.WIG 17 /r<br>ib<br>VEXTRACTPS r/m32, xmm1,<br>imm8 | A        | V/V                          | AVX                      | Extract one single-precision floating-point value from xmm1 at the offset specified by imm8 and store the result in reg or m32. Zero extend the results in 64-bit register if applicable. |

## Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:r/m (w) | ModRM:reg (r) | NA       | NA       |

## Description

Extracts a single-precision floating-point value from the source operand (second operand) at the 32-bit offset specified from imm8. Immediate bits higher than the most significant offset for the vector length are ignored.

The extracted single-precision floating-point value is stored in the low 32-bits of the destination operand

In 64-bit mode, destination register operand has default operand size of 64 bits. The upper 32-bits of the register are filled with zero. REX.W is ignored.

VEX.128 encoded version: When VEX.128.66.0F3A.W1 17 form is used in 64-bit mode with a general purpose register (GPR) as a destination operand, the packed single quantity is zero extended to 64 bits. VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

128-bit Legacy SSE version: When a REX.W prefix is used in 64-bit mode with a general purpose register (GPR) as a destination operand, the packed single quantity is zero extended to 64 bits.

The source register is an XMM register. Imm8[1:0] determine the starting DWORD offset from which to extract the 32-bit floating-point value.

If VEXTRACTPS is encoded with VEX.L= 1, an attempt to execute the instruction encoded with VEX.L= 1 will cause a #UD exception.

### Operation

### Description

Subtract pairs of adjacent single-precision floating-point values in the first source operand and second source operand and stores results in the destination.

Figure 5-13. VHSUBPS operation

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

#### Description

(register source form)

Select a single precision floating-point element from second source as indicated by Count\_S bits of the immediate operand and insert it into the first source at the location indicated by the Count\_D bits of the immediate operand. Store in the destination and zero out destination elements based on the ZMask bits of the immediate operand.

(memory source form)

Load a floating-point element from a 32-bit memory location and insert it into the first source at the location indicated by the Count\_D bits of the immediate operand. Store in the destination and zero out destination elements based on the ZMask bits of the immediate operand.

128-bit Legacy SSE version: The first source register is an XMM register. The second source operand is either an XMM register or a 32-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

VEX.128 encoded version. The destination and first source register is an XMM register. The second source operand is either an XMM register or a 32-bit memory location. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

If VINSERTPS is encoded with VEX.L= 1, an attempt to execute the instruction encoded with VEX.L= 1 will cause a #UD exception.

## Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

## Description

The instruction is functionally similar to VMOVDQU YMM, m256 for loading from memory. That is: 32 bytes of data starting at an address specified by the source memory operand (second operand) are fetched from memory and placed in a destination register (first operand). The source operand need not be aligned on a 32-byte boundary. Up to 64 bytes may be loaded from memory; this is implementation dependent.

This instruction may improve performance relative to VMOVDQU if the source operand crosses a cache line boundary. In situations that require the data loaded by VLDDQU be modified and stored to the same location, use VMOVDQU or VMOVDQA instead of VLDDQU. To move double quadwords to or from memory locations that are known to be aligned on 32-byte boundaries, use the VMOVDQA instruction.

## Implementation Notes

- If the source is aligned to a 32-byte boundary, based on the implementation, the 32 bytes may be loaded more than once. For that reason, the usage of VLDDQU should be avoided when using uncached or write-combining (WC) memory regions. For uncached or WC memory regions, keep using VMOVDQU.
- This instruction is a replacement for VMOVDQU (load) in situations where cache line splits significantly affect performance. It should not be used in situations where store-load forwarding is performance critical. If performance of store-load forwarding is critical to the application, use VMOVDQA store-load pairs when data is 256-bit aligned or VMOVDQU store-load pairs when data is 256-bit unaligned.

- If the memory address is not aligned on 32-byte boundary, some implementations may load up to 64 bytes and return 32 bytes in the destination. Some processor implementations may issue multiple loads to access the appropriate 32 bytes. Developers of multi-threaded or multi-processor software should be aware that on these processors the loads will be performed in a non-atomic way.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

### Instruction Operand Encoding

|   | Operand 1     | Operand2 | Operand3 | Operand4 |
|---|---------------|----------|----------|----------|
| A | ModRM:r/m (r) | NA       | NA       | NA       |

### Description

Loads the source operand into the MXCSR control/status register. The source operand is a 32-bit memory location.

The VLDMXCSR instruction is typically used in conjunction with the VSTMXCSR instruction for software that use instruction set extensions operating on the YMM state.

The default MXCSR value at reset is 1F80H.

If a VLDMXCSR instruction clears a SIMD floating-point exception mask bit and sets the corresponding exception flag bit, a SIMD floating-point exception will not be immediately generated. The exception will be generated only upon the execution of the next instruction that meets both conditions below:

- the instruction must operate on an XMM or YMM register operand,
- the instruction causes that particular SIMD floating-point exception to be reported.

This instruction's operation is the same in non-64-bit modes and 64-bit mode.

If VLDMXCSR is encoded with VEX.L= 1, an attempt to execute the instruction encoded with VEX.L= 1 will cause an #UD exception. VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

### Operation

MXCSR ← m32;

Instruction Operand Encoding<sup>1</sup>

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (r) | ModRM:r/m (r) | NA       | NA       |

## Description

Stores selected bytes from the source operand (first operand) into an 128-bit memory location. The mask operand (second operand) selects which bytes from the source operand are written to memory. The source and mask operands are XMM registers. The memory location specified by the effective address in the DI/EDI/RDI register (the default segment register is DS, but this may be overridden with a segment-override prefix). The memory location does not need to be aligned on a natural boundary. (The size of the store address depends on the address-size attribute.)

The most significant bit in each byte of the mask operand determines whether the corresponding byte in the source operand is written to the corresponding byte location in memory: 0 indicates no write and 1 indicates write.

The MASKMOVDQU instruction generates a non-temporal hint to the processor to minimize cache pollution. The non-temporal hint is implemented by using a write combining (WC) memory type protocol (see "Caching of Temporal vs. Non-Temporal Data" in Chapter 10, of the IA-32 Intel® Architecture Software Developer's Manual, Volume 1). Because the WC protocol uses a weakly-ordered memory consistency model, a fencing operation implemented with the SFENCE or MFENCE instruction

---

1. ModRM.MOD = 011B required

should be used in conjunction with MASKMOVDQU instructions if multiple processors might use different memory types to read/write the destination memory locations.

Behavior with a mask of all 0s is as follows:

- No data will be written to memory.
- Signaling of breakpoints (code or data) is not guaranteed; different processor implementations may signal or not signal these breakpoints.
- Exceptions associated with addressing memory and page faults may still be signaled (implementation dependent).
- If the destination memory region is mapped as UC or WP, enforcement of associated semantics for these memory types is not guaranteed (that is, is reserved) and is implementation-specific.

Instruction behavior on alignment check reporting with mask bits of less than all 1s are the same as with mask bits of all 1s.

The MASKMOVDQU instruction can be used to improve performance of algorithms that need to merge data on a byte-by-byte basis. MASKMOVDQU should not cause a read for ownership; doing so generates unnecessary bandwidth since data is to be written directly using the bytemask without allocating old data prior to the store.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

If VMASKMOVDQU is encoded with VEX.L= 1, an attempt to execute the instruction encoded with VEX.L= 1 will cause an #UD exception.

## Operation

### Description

Conditionally moves packed data elements from the second source operand into the corresponding data element of the destination operand, depending on the mask bits associated with each data element. The mask bits are specified in the first source operand.

The mask bit for each data element is the most significant bit of that element in the first source operand. If a mask is 1, the corresponding data element is copied from the second source operand to the destination operand. If the mask is 0, the corresponding data element is set to zero in the load form of these instructions, and unmodified in the store form.

The second source operand is a memory address for the load form of these instructions. The destination operand is a memory address for the store form of these instructions. The other operands are both XMM registers (for VEX.128 version) or YMM registers (for VEX.256 version).

Faults occur only due to mask-bit required memory accesses that caused the faults. Faults will not occur due to referencing any memory location if the corresponding mask bit for that memory location is 0. For example, no faults will be detected if the mask bits are all zero.

Unlike previous MASKMOV instructions (MASKMOVQ and MASKMOVDQU), a nontemporal hint is not applied to these instructions

Instruction behavior on alignment check reporting with mask bits of less than all 1s are the same as with mask bits of all 1s.

VMASKMOV should not be used to access memory mapped I/O and un-cached memory as the access and the ordering of the individual loads or stores it does is implementation specific.

In cases where mask bits indicate data should not be loaded or stored paging A and D bits will be set in an implementation dependent way. However, A and D bits are always set for pages where data is actually loaded/stored.

Note: for load forms, the first source (the mask) is encoded in VEX.vvvv; the second source is encoded in `rm_field`, and the destination register is encoded in `reg_field`.

Note: for store forms, the first source (the mask) is encoded in VEX.vvvv; the second source register is encoded in `reg_field`, and the destination memory location is encoded in `rm_field`.

### Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Performs an SIMD compare of the packed double-precision floating-point values in the first source operand and the second source operand and returns the maximum value for each pair of values to the destination operand.

If the values being compared are both 0.0s (of either sign), the value in the second operand (source operand) is returned. If a value in the second operand is an SNaN, that SNaN is forwarded unchanged to the destination (that is, a QNaN version of the SNaN is not returned).

If only one value is a NaN (SNaN or QNaN) for this instruction, the second operand (source operand), either a NaN or a valid floating-point value, is written to the result. If instead of this behavior, it is required that the NaN source operand (from either the first or second operand) be returned, the action of MAXPD can be emulated using a sequence of instructions, such as, a comparison followed by AND, ANDN and OR.

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

### Operation

## Description

Performs an SIMD compare of the packed single-precision floating-point values in the first source operand and the second source operand and returns the maximum value for each pair of values to the destination operand.

If the values being compared are both 0.0s (of either sign), the value in the second operand (source operand) is returned. If a value in the second operand is an SNaN, that SNaN is forwarded unchanged to the destination (that is, a QNaN version of the SNaN is not returned).

If only one value is a NaN (SNaN or QNaN) for this instruction, the second operand (source operand), either a NaN or a valid floating-point value, is written to the result. If instead of this behavior, it is required that the NaN source operand (from either the first or second operand) be returned, the action of MAXPS can be emulated using a sequence of instructions, such as, a comparison followed by AND, ANDN and OR.

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

### Operation

### Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Compares the low double-precision floating-point values in the first source operand and second the source operand, and returns the maximum value to the low quadword of the destination operand. The second source operand can be an XMM register or a 64-bit memory location. The first source and destination operands are XMM registers. When the second source operand is a memory operand, only 64 bits are accessed. The high quadword of the destination operand is copied from the same bits of first source operand.

If the values being compared are both 0.0s (of either sign), the value in the second source operand is returned. If a value in the second source operand is an SNaN, that SNaN is returned unchanged to the destination (that is, a QNaN version of the SNaN is not returned).

If only one value is a NaN (SNaN or QNaN) for this instruction, the second source operand, either a NaN or a valid floating-point value, is written to the result. If instead of this behavior, it is required that the NaN of either source operand be returned, the action of MAXSD can be emulated using a sequence of instructions, such as, a comparison followed by AND, ANDN and OR.

The second source operand can be an XMM register or a 64-bit memory location. The first source and destination operands are XMM registers.

## INSTRUCTION SET REFERENCE

128-bit Legacy SSE version: The destination and first source operand are the same. Bits (VLMAX-1:64) of the corresponding YMM destination register remain unchanged.  
VEX.128 encoded version: Bits (127:64) of the XMM register destination are copied from corresponding bits in the first source operand. Bits (VLMAX-1:128) of the destination YMM register are zeroed.

### Operation

### Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Performs an SIMD compare of the packed double-precision floating-point values in the first source operand and the second source operand and returns the minimum value for each pair of values to the destination operand.

If the values being compared are both 0.0s (of either sign), the value in the second operand (source operand) is returned. If a value in the second operand is an SNaN, that SNaN is forwarded unchanged to the destination (that is, a QNaN version of the SNaN is not returned).

If only one value is a NaN (SNaN or QNaN) for this instruction, the second operand (source operand), either a NaN or a valid floating-point value, is written to the result. If instead of this behavior, it is required that the NaN source operand (from either the first or second operand) be returned, the action of MINPD can be emulated using a sequence of instructions, such as, a comparison followed by AND, ANDN and OR.

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

### Operation

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |
| B | ModRM:r/m (w) | ModRM:reg (r) | NA       | NA       |

### Description

Moves 2 or 4 double-precision floating-point values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load an XMM or YMM register from an 128-bit or 256-bit memory location, to store the contents of an XMM or YMM register into a 128-bit or 256-bit memory location, or to move data between two XMM or two YMM registers. When the source or destina-

tion operand is a memory operand, the operand must be aligned on a 16-byte (128-bit version) or 32-byte (VEX.256 encoded version) boundary or a general-protection exception (#GP) will be generated. To move double-precision floating-point values to and from unaligned memory locations, use the VMOVUPD instruction.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

VEX.256 encoded version:

Moves 256 bits of packed double-precision floating-point values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load a YMM register from a 256-bit memory location, to store the contents of a YMM register into a 256-bit memory location, or to move data between two YMM registers. When the source or destination operand is a memory operand, the operand must be aligned on a 32-byte boundary or a general-protection exception (#GP) will be generated. To move single-precision floating-point values to and from unaligned memory locations, use the VMOVUPD instruction.

128-bit versions:

Moves 128 bits of packed double-precision floating-point values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load an XMM register from a 128-bit memory location, to store the contents of an XMM register into a 128-bit memory location, or to move data between two XMM registers. When the source or destination operand is a memory operand, the operand must be aligned on a 16-byte boundary or a general-protection exception (#GP) will be generated. To move single-precision floating-point values to and from unaligned memory locations, use the VMOVUPD instruction.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register destination are zeroed.

| B | ModRM:r/m (w) | ModRM:reg (r) | NA       | NA       |

## Description

Moves 4 or 8 single-precision floating-point values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load an XMM or YMM register from an 128-bit or 256-bit memory location, to store the contents of an XMM or YMM register into a 128-bit or 256-bit memory location, or to move data between two XMM or two YMM registers. When the source or destination operand is a memory operand, the operand must be aligned on a 16-byte (128-

bit version) or 32-byte (VEX.256 encoded version) boundary or a general-protection exception (#GP) will be generated. To move single-precision floating-point values to and from unaligned memory locations, use the VMOVUPS instruction.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

VEX.256 encoded version:

Moves 256 bits of packed single-precision floating-point values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load a YMM register from a 256-bit memory location, to store the contents of a YMM register into a 256-bit memory location, or to move data between two YMM registers.

128-bit versions:

Moves 128 bits of packed single-precision floating-point values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load an XMM register from a 128-bit memory location, to store the contents of an XMM register into a 128-bit memory location, or to move data between two XMM registers. When the source or destination operand is a memory operand, the operand must be aligned on a 16-byte boundary or a general-protection exception (#GP) will be generated. To move single-precision floating-point values to and from unaligned memory locations, use the VMOVUPS instruction.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed.

## Operation

### Description

#### MOVD/Q with XMM destination:

Moves a dword integer from the source operand and stores it in the low 32-bits of the destination XMM register. The upper bits of the destination are zeroed. The source

## INSTRUCTION SET REFERENCE

operand can be a 32-bit register or 32-bit memory location. A REX.W prefix promotes this to copy qword integers.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed.

Note: In 32-bit mode, the functionality of VMOVQ is not encodable, the instruction bytes that encode VMOVQ (VEX.W=1) is executed as VMOVD (treating VEX.W = 0 instead).

### MOVD/Q with r32/m32 or r64/m64 destination:

Stores 32 (64) bits from the low bits of the source XMM register.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

If VMOVD or VMOVQ is encoded with VEX.L= 1, an attempt to execute the instruction encoded with VEX.L= 1 will cause an #UD exception.

### Operation

| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |
| B | ModRM:r/m (w) | ModRM:reg (r) | NA       | NA       |

## Description

Copies a quadword from the source operand (second operand) to the destination operand (first operand). The source and destination operands can be an XMM register or a 64-bit memory locations. This instruction can be used to move data between two XMM registers or between an XMM register and a 64-bit memory location. The instruction cannot be used to transfer data between memory locations.

When the source operand is an XMM register, the low quadword is moved; when the destination operand is an XMM register, the quadword is stored to the low quadword of the register, and the high quadword is cleared to all 0s.

Note: In VEX.128.66.0F D6 instruction version, VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

Note: In VEX.128.F3.0F 7E version, VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

If VMOVQ is encoded with VEX.L= 1, an attempt to execute the instruction encoded with VEX.L= 1 will cause an #UD exception.

### Description

VEX.256 encoded version:

Duplicates even-indexed double-precision floating-point values from the source operand (second operand).

128-bit versions:

Duplicates a single double-precision floating-point value into the destination.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

### Description

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

VEX.256 encoded version:

Moves 256 bits of packed integer values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load a YMM register from a 256-bit memory location, to store the contents of a YMM register into a 256-bit memory location, or to move data between two YMM registers.

When the source or destination operand is a memory operand, the operand must be aligned on a 32-byte boundary or a general-protection exception (#GP) will be generated. To move integer data to and from unaligned memory locations, use the VMOVDQU instruction.

128-bit versions:

Moves 128 bits of packed integer values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load an XMM register from a 128-bit memory location, to store the contents of an XMM register into a 128-bit memory location, or to move data between two XMM registers.

When the source or destination operand is a memory operand, the operand must be aligned on a 16-byte boundary or a general-protection exception (#GP) will be generated. To move integer data to and from unaligned memory locations, use the VMOVDQU instruction.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed.

## Description

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

**VEX.256 encoded version:**

Moves 256 bits of packed integer values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load a YMM register from a 256-bit memory location, to store the contents of a YMM register into a 256-bit memory location, or to move data between two YMM registers.

### **128-bit versions:**

Moves 128 bits of packed integer values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load an XMM register from a 128-bit memory location, to store the contents of an XMM register into a 128-bit memory location, or to move data between two XMM registers.

**128-bit Legacy SSE version:** Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

When the source or destination operand is a memory operand, the operand may be unaligned to any alignment without causing a general-protection exception (#GP) to be generated

**VEX.128 encoded version:** Bits (VLMAX-1:128) of the destination YMM register are zeroed.

### Description

This instruction cannot be used for memory to register moves.

#### 128-bit two-argument form:

Moves two packed single-precision floating-point values from the high quadword of the second XMM argument (second operand) to the low quadword of the first XMM register (first argument). The high quadword of the destination operand is left unchanged. Bits (VLMAX-1:64) of the corresponding YMM destination register are unmodified.

#### 128-bit three-argument form

Moves two packed single-precision floating-point values from the high quadword of the third XMM argument (third operand) to the low quadword of the destination (first operand). Copies the high quadword from the second XMM argument (second operand) to the high quadword of the destination (first operand). Bits (VLMAX-1:128) of the destination YMM register are zeroed.

If VMOVHPLPS is encoded with VEX.L= 1, an attempt to execute the instruction encoded with VEX.L= 1 will cause a #UD exception.

| C | ModRM:r/m (w)    | ModRM:reg (r) | NA            | NA       |

### Description

This instruction cannot be used for register to register or memory to memory moves.

#### 128-bit Legacy SSE load:

Moves a double-precision floating-point value from the source 64-bit memory operand and stores it in the high 64-bits of the destination XMM register. The lower 64bits of the XMM register are preserved. The upper 128-bits of the corresponding YMM destination register are preserved.

#### VEX.128 encoded load:

Loads a double-precision floating-point value from the source 64-bit memory operand (third operand) and stores it in the upper 64-bits of the destination XMM register (first operand). The low 64-bits from second XMM register (second operand)

are stored in the lower 64-bits of the destination. The upper 128-bits of the destination YMM register are zeroed.

### 128-bit store:

Stores a double-precision floating-point value from the high 64-bits of the XMM register source (second operand) to the 64-bit memory location (first operand).

Note: `VMOVHPD (store) (VEX.128.66.0F 17 /r)` is legal and has the same behavior as the existing `66 0F 17 store`. For `VMOVHPD (store) (VEX.128.66.0F 17 /r)` instruction version, `VEX.vvvv` is reserved and must be `1111b` otherwise instruction will `#UD`.

If `VMOVHPD` is encoded with `VEX.L= 1`, an attempt to execute the instruction encoded with `VEX.L= 1` will cause an `#UD` exception.

| C | ModRM:r/m (w)    | ModRM:reg (r) | NA            | NA       |

## Description

This instruction cannot be used for register to register or memory to memory moves.

**128-bit Legacy SSE load:**

Moves two packed single-precision floating-point values from the source 64-bit memory operand and stores them in the high 64-bits of the destination XMM register. The lower 64bits of the XMM register are preserved. The upper 128-bits of the corresponding YMM destination register are preserved.

**VEX.128 encoded load:**

Loads two single-precision floating-point values from the source 64-bit memory operand (third operand) and stores it in the upper 64-bits of the destination XMM register (first operand). The low 64-bits from second XMM register (second operand)

are stored in the lower 64-bits of the destination. The upper 128-bits of the destination YMM register are zeroed.

### 128-bit store:

Stores two packed single-precision floating-point values from the high 64-bits of the XMM register source (second operand) to the 64-bit memory location (first operand).

Note: `VMOVHPS (store) (VEX.NDS.128.0F 17 /r)` is legal and has the same behavior as the existing `0F 17 store`. For `VMOVHPS (store) (VEX.NDS.128.0F 17 /r)` instruction version, `VEX.vvvv` is reserved and must be `1111b` otherwise instruction will `#UD`.

If `VMOVHPS` is encoded with `VEX.L= 1`, an attempt to execute the instruction encoded with `VEX.L= 1` will cause an `#UD` exception.

| VEX.NDS.128.0F.WIG 16 /r<br>VMOVLHPS xmm1, xmm2,<br>xmm3 |          | V/V                          | AVX                      | Merge two packed single-precision floating-point values from low quadword of xmm3 and low quadword of xmm2. |

### Instruction Operand Encoding<sup>1</sup>

|   | Operand 1     | Operand2      | Operand3      | Operand4 |
|---|---------------|---------------|---------------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w) | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

This instruction cannot be used for memory to register moves.

#### 128-bit two-argument form:

Moves two packed single-precision floating-point values from the low quadword of the second XMM argument (second operand) to the high quadword of the first XMM register (first argument). The low quadword of the destination operand is left unchanged. The upper 128 bits of the corresponding YMM destination register are unmodified.

#### 128-bit three-argument form

Moves two packed single-precision floating-point values from the low quadword of the third XMM argument (third operand) to the high quadword of the destination (first operand). Copies the low quadword from the second XMM argument (second operand) to the low quadword of the destination (first operand). The upper 128-bits of the destination YMM register are zeroed.

If VMOVLHPS is encoded with VEX.L= 1, an attempt to execute the instruction encoded with VEX.L= 1 will cause an #UD exception.

### Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |
| C | ModRM:r/m (w)    | ModRM:reg (r) | NA            | NA       |

### Description

This instruction cannot be used for register to register or memory to memory moves.

#### 128-bit Legacy SSE load:

Moves a double-precision floating-point value from the source 64-bit memory operand and stores it in the low 64-bits of the destination XMM register. The upper 64bits of the XMM register are preserved. The upper 128-bits of the corresponding YMM destination register are preserved.

#### VEX.128 encoded load:

Loads a double-precision floating-point value from the source 64-bit memory operand (third operand), merges it with the upper 64-bits of the first source XMM register (second operand), and stores it in the low 128-bits of the destination XMM

register (first operand). The upper 128-bits of the destination YMM register are zeroed.

### 128-bit store:

Stores a double-precision floating-point value from the low 64-bits of the XMM register source (second operand) to the 64-bit memory location (first operand).

Note: `VMOVLPD (store) (VEX.128.66.0F 13 /r)` is legal and has the same behavior as the existing `66 0F 13 store`. For `VMOVLPD (store) (VEX.128.66.0F 13 /r)` instruction version, `VEX.vvvv` is reserved and must be `1111b` otherwise instruction will `#UD`.

If `VMOVLPD` is encoded with `VEX.L= 1`, an attempt to execute the instruction encoded with `VEX.L= 1` will cause an `#UD` exception.

| C | ModRM:r/m (w)    | ModRM:reg (r) | NA            | NA       |

### Description

This instruction cannot be used for register to register or memory to memory moves.

#### 128-bit Legacy SSE load:

Moves two packed single-precision floating-point values from the source 64-bit memory operand and stores them in the low 64-bits of the destination XMM register. The upper 64bits of the XMM register are preserved. The upper 128-bits of the corresponding YMM destination register are preserved.

#### VEX.128 encoded load:

Loads two packed single-precision floating-point values from the source 64-bit memory operand (third operand), merges them with the upper 64-bits of the first source XMM register (second operand), and stores them in the low 128-bits of the

destination XMM register (first operand). The upper 128-bits of the destination YMM register are zeroed.

### 128-bit store:

Loads two packed single-precision floating-point values from the low 64-bits of the XMM register source (second operand) to the 64-bit memory location (first operand).

Note: `VMOVLPS (store) (VEX.128.0F 13 /r)` is legal and has the same behavior as the existing `0F 13 store`. For `VMOVLPS (store) (VEX.128.0F 13 /r)` instruction version, `VEX.vvvv` is reserved and must be `1111b` otherwise instruction will `#UD`.

If `VMOVLPS` is encoded with `VEX.L= 1`, an attempt to execute the instruction encoded with `VEX.L= 1` will cause an `#UD` exception.

### Operation

|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

### Description

Extracts the sign bits from the packed double-precision floating-point values in the source operand (second operand), formats them into a 2- or 4-bit mask, and stores the mask in the destination operand (first operand). The source operand is an XMM or YMM register, and the destination operand is a general-purpose register. The mask is stored in the 2 or 4 low-order bits of the destination operand. The upper bits of the destination operand beyond the mask are filled with zeros.

In 64-bit mode, the default operand size of the destination register is 64 bit.

VEX.256 encoded version: The source operand is a YMM register. The destination operand is a general purpose register.

128-bit versions: The source operand is a YMM register. The destination operand is a general purpose register.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

|---|---------------|---------------|----------|----------|
| A | ModRM:r/m (w) | ModRM:reg (r) | NA       | NA       |

## Description

Moves the packed integers in the source operand (second operand) to the destination operand (first operand) using a non-temporal hint to prevent caching of the data during the write to memory. The source operand is an XMM register or YMM register, which is assumed to contain integer data (packed bytes, words, doublewords, or quadwords). The destination operand is a 128-bit or 256-bit memory location. The memory operand must be aligned on a 16-byte (128-bit version) or 32-byte (VEX.256 encoded version) boundary otherwise a general-protection exception (#GP) will be generated.

The non-temporal hint is implemented by using a write combining (WC) memory type protocol when writing the data to memory. Using this protocol, the processor does not write the data into the cache hierarchy, nor does it fetch the corresponding cache line from memory into the cache hierarchy. The memory type of the region being written to can override the non-temporal hint, if the memory address specified for the non-temporal store is in an uncacheable (UC) or write protected (WP) memory region. For more information on non-temporal stores, see “Caching of Temporal vs. Non-Temporal Data” in Chapter 10 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1.

1. ModRM.MOD = 011B required

## INSTRUCTION SET REFERENCE

Because the WC protocol uses a weakly-ordered memory consistency model, a fencing operation implemented with the SFENCE or MFENCE instruction should be used in conjunction with VMOVNTDQ instructions if multiple processors might use different memory types to read/write the destination memory locations.

Note: In VEX-128 encoded versions, VEX.vvvv is reserved and must be 1111b, VEX.L must be 0; otherwise instructions will #UD.

## Description

MOVNTDQA loads a double quadword from the source operand (second operand) to the destination operand (first operand) using a non-temporal hint if the memory source is WC (write combining) memory type. For WC memory type, the non-temporal hint may be implemented by loading a temporary internal buffer with the equivalent of an aligned cache line without filling this data to the cache. Any memory-type aliased lines in the cache will be snooped and flushed. Subsequent MOVNTDQA reads to unread portions of the WC cache line will receive data from the temporary internal buffer if data is available. The temporary internal buffer may be flushed by the processor at any time for any reason, for example:

- A load operation other than a MOVNTDQA which references memory already resident in a temporary internal buffer.
- A non-WC reference to memory already resident in a temporary internal buffer.
- Interleaving of reads and writes to a single temporary internal buffer.
- Repeated (V)MOVNTDQA loads of a particular 16-byte item in a streaming line.
- Certain micro-architectural conditions including resource shortages, detection of a mis-speculation condition, and various fault conditions

The non-temporal hint is implemented by using a write combining (WC) memory type protocol when reading the data from memory. Using this protocol, the processor

1. ModRM.MOD = 011B required

does not read the data into the cache hierarchy, nor does it fetch the corresponding cache line from memory into the cache hierarchy. The memory type of the region being read can override the non-temporal hint, if the memory address specified for the non-temporal read is not a WC memory region. Information on non-temporal reads and writes can be found in “Caching of Temporal vs. Non-Temporal Data” in Chapter 10 in the Intel® 64 and IA-32 Architecture Software Developer’s Manual, Volume 3A.

Because the WC protocol uses a weakly-ordered memory consistency model, a fencing operation implemented with a MFENCE instruction should be used in conjunction with MOVNTDQA instructions if multiple processors might use different memory types for the referenced memory locations or to synchronize reads of a processor with writes by other agents in the system. A processor’s implementation of the streaming load hint does not override the effective memory type, but the implementation of the hint is processor dependent. For example, a processor implementation may choose to ignore the hint and process the instruction as a normal MOVDQA for any memory type. Alternatively, another implementation may optimize cache reads generated by MOVNTDQA on WB memory type to reduce cache evictions.

The 128-bit (V)MOVNTDQA addresses must be 16-byte aligned or the instruction will cause a #GP.

Note: In VEX-128 encoded versions, VEX.vvvv is reserved and must be 1111b, VEX.L must be 0; otherwise instructions will #UD.

### Description

Moves the packed double-precision floating-point values in the source operand (second operand) to the destination operand (first operand) using a non-temporal hint to prevent caching of the data during the write to memory. The source operand is an XMM register or YMM register, which is assumed to contain packed double-precision, floating-pointing data. The destination operand is a 128-bit or 256-bit memory location. The memory operand must be aligned on a 16-byte (128-bit version) or 32-byte (VEX.256 encoded version) boundary otherwise a general-protection exception (#GP) will be generated.

The non-temporal hint is implemented by using a write combining (WC) memory type protocol when writing the data to memory. Using this protocol, the processor does not write the data into the cache hierarchy, nor does it fetch the corresponding cache line from memory into the cache hierarchy. The memory type of the region being written to can override the non-temporal hint, if the memory address specified for the non-temporal store is in an uncacheable (UC) or write protected (WP) memory region. For more information on non-temporal stores, see "Caching of

1. ModRM.MOD = 011B required

## INSTRUCTION SET REFERENCE

Temporal vs. Non-Temporal Data” in Chapter 10 in the IA-32 Intel Architecture Software Developer’s Manual, Volume 1.

Because the WC protocol uses a weakly-ordered memory consistency model, a fencing operation implemented with the SFENCE or MFENCE instruction should be used in conjunction with MOVNTPD instructions if multiple processors might use different memory types to read/write the destination memory locations.

Note: In VEX-128 encoded versions, VEX.vvvv is reserved and must be 1111b, VEX.L must be 0; otherwise instructions will #UD.

| E | ModRM:r/m (w)    | VEX.vvvv (r)  | ModRM:reg (r) | NA       |

## Description

MOVSD moves a scalar double-precision floating-point value from the source operand (second operand) to the destination operand (first operand). The source and destination operands can be XMM registers or 64-bit memory locations. This instruc-

tion can be used to move a double-precision floating-point value to and from the low quadword of an XMM register and a 64-bit memory location, or to move a double-precision floating-point value between the low quadwords of two XMM registers. The instruction cannot be used to transfer data between memory locations.

For non-VEX encoded instruction syntax and when the source and destination operands are XMM registers, the high quadword of the destination operand remains unchanged. When the source operand is a memory location and destination operand is an XMM registers, the high quadword of the destination operand is cleared to all 0s.

Note: For the “VMOVSD m64, xmm1” (memory store form) instruction version, VEX.vvvv is reserved and must be 1111b, otherwise instruction will #UD.

Note: For the “VMOVSD xmm1, m64” (memory load form) instruction version, VEX.vvvv is reserved and must be 1111b otherwise instruction will #UD.

VEX encoded instruction syntax supports two source operands and a destination operand if ModR/M.mod field is 11B. VEX.vvvv is used to encode the first source operand (the second operand). The low 128 bits of the destination operand stores the result of merging the low quadword of the second source operand with the quad word in bits 127:64 of the first source operand. The upper bits of the destination operand are cleared.

## Description

MOVSS moves a scalar single-precision floating-point value from the source operand (second operand) to the destination operand (first operand). The source and destination operands can be XMM registers or 32-bit memory locations. This instruction can

be used to move a single-precision floating-point value to and from the low doubleword of an XMM register and a 32-bit memory location, or to move a single-precision floating-point value between the low doublewords of two XMM registers. The instruction cannot be used to transfer data between memory locations.

For non-VEX encoded syntax and when the source and destination operands are XMM registers, the high doublewords of the destination operand remains unchanged. When the source operand is a memory location and destination operand is an XMM registers, the high doublewords of the destination operand is cleared to all 0s.

Note: For the “VMOVSS m32, xmm1” (memory store form) instruction version, VEX.vvvv is reserved and must be 1111b otherwise instruction will #UD.

Note: For the “VMOVSS xmm1, m32” (memory load form) instruction version, VEX.vvvv is reserved and must be 1111b otherwise instruction will #UD.

VEX encoded instruction syntax supports two source operands and a destination operand if ModR/M.mod field is 11B. VEX.vvvv is used to encode the first source operand (the second operand). The low 128 bits of the destination operand stores the result of merging the low dword of the second source operand with three dwords in bits 127:32 of the first source operand. The upper bits of the destination operand are cleared.

### Operation

**MOVSS (Legacy SSE version when the source and destination operands are both XMM registers)**

## Description

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b otherwise instructions will #UD.

**VEX.256 encoded version:**

Moves 256 bits of packed double-precision floating-point values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load a YMM register from a 256-bit memory location, to store the contents of a YMM register into a 256-bit memory location, or to move data between two YMM registers.

### **128-bit versions:**

Moves 128 bits of packed double-precision floating-point values from the source operand (second operand) to the destination operand (first operand). This instruction can be used to load an XMM register from a 128-bit memory location, to store the contents of an XMM register into a 128-bit memory location, or to move data between two XMM registers.

**128-bit Legacy SSE version:** Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

When the source or destination operand is a memory operand, the operand may be unaligned on a 16-byte boundary without causing a general-protection exception (#GP) to be generated

**VEX.128 encoded version:** Bits (VLMAX-1:128) of the destination YMM register are zeroed.

| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

MPSADBW sums the absolute difference of 4 unsigned bytes selected by immediate bits 0-1 from the second source with sequential groups of 4 unsigned bytes in the first source operand. The source bytes from the first source operand start at an offset determined by bit 2 of the immediate. The operation is repeated 8 times, each time using the same second source input but selecting the group of 4 bytes starting at the next higher byte in the first source. Each 16-bit sum is written to dest.

The first source and destination operands are XMM registers. The second source operand is either an XMM register or a 128-bit memory location.

128-bit Legacy SSE version: The first source and destination are the same. Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed.

If VMPSADBW is encoded with VEX.L= 1, an attempt to execute the instruction encoded with VEX.L= 1 will cause an #UD exception.

### Description

Performs a SIMD Multiply of the two or four packed double-precision floating-point values from the first Source operand to the Second Source operand, and stores the packed double-precision floating-point results in the destination operand.

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the destination YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Multiplies the low double-precision floating-point value in the second source operand by the low double-precision floating-point value in the first source operand, and stores the double-precision floating-point result in the destination operand. The second source operand can be an XMM register or a 64-bit memory location. The first source operand and the destination operands are XMM registers. The high quadword of the destination operand is copied from the high bits of the first source operand. See Figure 11-4 in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1, for an illustration of a scalar double-precision floating-point operation.

128-bit Legacy SSE version: The first source operand and the destination operand are the same. Bits (VLMAX-1:64) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed.

### Operation

## Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

## Description

Performs a bitwise logical OR of the two or four packed double-precision floating-point values from the first source operand and the second source operand, and stores the result in the destination operand

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the destination YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

If VORPD is encoded with VEX.L= 1, an attempt to execute the instruction encoded with VEX.L= 1 will cause an #UD exception.

### Operation

#### **VORPD (VEX.256 encoded version)**

| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

## Description

Performs a bitwise logical OR of the four or eight packed single-precision floating-point values from the first source operand and the second source operand, and stores the result in the destination operand

VEX.256 Encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the destination YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

If VORPS is encoded with VEX.L= 1, an attempt to execute the instruction encoded with VEX.L= 1 will cause an #UD exception.

|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

## Description

PABSB/W/D computes the absolute value of each data element of the source operand and stores the UNSIGNED results in the destination operand. PABSB operates on signed bytes, PABSW operates on signed 16-bit words, and PABSD operates on signed 32-bit integers. The source is an XMM register or a 128-bit memory location. The destination operand is an XMM register.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.vvvv is reserved and must be 1111b, VEX.L must be 0; otherwise instructions will #UD.

### Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Converts packed signed word integers into packed signed byte integers (PACKSSWB) or converts packed signed doubleword integers into packed signed word integers (PACKSSDW), using saturation to handle overflow conditions. See Figure 5-17 for an example of the packing operation.

Figure 5-17. PACKSSDW Instruction Operation using 64-bit Operands

The PACKSSWB instruction converts 8 signed word integers from the first source operand and 8 signed word integers from the second source operand into 16 signed byte integers and stores the result in the destination operand. If a signed word integer value is beyond the range of a signed byte integer (that is, greater than 7FH for a positive integer or greater than 80H for a negative integer), the saturated signed byte integer value of 7FH or 80H, respectively, is stored in the destination.

The PACKSSDW instruction packs 4 signed doublewords from the first source operand and 4 signed doublewords from the second source operand into 8 signed words in the destination operand (see Figure 5-17).

If a signed doubleword integer value is beyond the range of a signed word (that is, greater than 7FFFH for a positive integer or greater than 8000H for a negative integer), the saturated signed word integer value of 7FFFH or 8000H, respectively, is stored into the destination.

When operating on 128-bit operands, the first source and destination operands are XMM registers, and the second source operand can be either an XMM register or a 128-bit memory location.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

## Description

packuswb:

Converts 8 signed word integers from the second source operand and 8 signed word integers from the first source operand into 8 unsigned byte integers and stores the result in the destination operand. (See Figure 5-17 for an example of the packing

operation.) If a signed word integer value is beyond the range of an unsigned byte integer (that is, greater than FFH or less than 00H), the saturated unsigned byte integer value of FFH or 00H, respectively, is stored in the destination.

The first source operand and destination operand must be an XMM register and the second source operand can be either an XMM register or a 128-bit memory location.

packusdw:

Converts packed signed doubleword integers into packed unsigned word integers using unsigned saturation to handle overflow conditions. If the signed doubleword value is beyond the range of an unsigned word (that is, greater than FFFFH or less than 0000H), the saturated unsigned word integer value of FFFFH or 0000H, respectively stored in the destination.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

### Operation

**SaturateSignedWordToUnsignedByte(SRC)**

```
{

## Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

## Description

Adds the packed byte, word, doubleword, or quadword integers in the first source operand to the second source operand and stores the result in the destination operand. The second source operand is an XMM register or an 128-bit memory location. The first source operand and destination operand are XMM registers. When a result is too large to be represented in the 8/16/32/64 integer (overflow), the result is wrapped around and the low bits are written to the destination element (that is, the carry is ignored).

Note that these instructions can operate on either unsigned or signed (two's complement notation) integers; however, it does not set bits in the EFLAGS register to indicate overflow and/or a carry. To prevent undetected overflow conditions, software must control the ranges of the values operated on.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

### Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Performs a SIMD add of the packed signed integers from the second source operand and the first source operand and stores the packed integer results in the destination operand. See Figure 9-4 in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1, for an illustration of a SIMD operation.

Overflow is handled with signed saturation, as described in the following paragraphs. The second source operand can be either an XMM register or a 128-bit memory location. The first source and destination operands are XMM registers.

The PADDSB instruction adds packed signed byte integers. When an individual byte result is beyond the range of a signed byte integer (that is, greater than 7FH or less than 80H), the saturated value of 7FH or 80H, respectively, is written to the destination operand.

The PADDSW instruction adds packed signed word integers. When an individual word result is beyond the range of a signed word integer (that is, greater than 7FFFH or less than 8000H), the saturated value of 7FFFH or 8000H, respectively, is written to the destination operand.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

### Description

Performs a SIMD add of the packed unsigned integers from the second source operand and the first source operand and stores the packed integer results in the destination operand. See Figure 9-4 in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1, for an illustration of a SIMD operation. Overflow is handled with unsigned saturation, as described in the following paragraphs.

The first source operand and the destination operands are XMM registers. The second source operand is either an XMM register or a 128-bit memory location.

The PADDUSB instruction adds packed unsigned byte integers. When an individual byte result is beyond the range of an unsigned byte integer (that is, greater than FFH), the saturated value of FFH is written to the destination operand. The PADDUSW instruction adds packed unsigned word integers. When an individual word result is

beyond the range of an unsigned word integer (that is, greater than FFFFH), the saturated value of FFFFH is written to the destination operand.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

### Operation

|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

## Description

PALIGNR concatenates the first source operand and the second source operand into an intermediate composite, shifts the composite at byte granularity to the right by a constant immediate, and extracts the right aligned result into the destination. The first source and destination operand are XMM registers. The second source operand can be an XMM register or a 128-bit memory location. The immediate value is considered unsigned. Immediate shift counts larger than 32 for 128-bit operands produces a zero result.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

## Operation

**PALIGNR**

```
temp1[255:0] ← CONCATENATE(DEST, SRC) >> (imm8*8)
```

```
DEST[127:0] ← temp1[127:0]
```

## Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

## Description

Performs a SIMD average of the packed unsigned integers from the second source operand and the first source operand and stores the results in the destination operand. For each corresponding pair of data elements in the first and second source operands, the elements are added together, a 1 is added to the temporary sum, and that result is shifted right one bit position. The destination and first source operands are XMM registers. The second source operand is an XMM register or a 128-bit memory location.

The PAVGB instruction operates on packed unsigned bytes and the PAVGW instruction operates on packed unsigned words.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

### Operation

## PBLENDVB - Variable Blend Packed Bytes

| Opcode/<br>Instruction   | Op<br>En | 64/32 bit<br>Mode<br>Support | CPUID<br>Feature<br>Flag | Description   |
|--|----------|------------------------------|--------------------------|---|
| 66 0F 38 10 /r<br>PBLENDVB xmm1,<br>xmm2/m128, <XMM0>                            | A        | V/V                          | SSE4_1                   | Select byte values from xmm1 and xmm2/m128 using mask bits in the implicit mask register, XMM0, and store the values into xmm1  |
| VEX.NDS.128.66.0F3A.W0<br>4C /r /is4<br>VPBLENDVB xmm1, xmm2,<br>xmm3/m128, xmm4 | B        | V/V                          | AVX                      | Select byte values from xmm2 and xmm3/m128 using mask bits in the specified mask register, xmm4, and store the values into xmm1 |

## Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4  |
|---|------------------|---------------|---------------|-----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA        |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | imm8[7:4] |

## Description

Conditionally copy byte elements from the second source operand and the first source operand depending on mask bits defined in the mask register operand. The mask bits are the most significant bit in each byte element of the mask register.

Each byte element of the destination operand is copied from:

- the corresponding byte element in the second source operand, If a mask bit is "1"; or
- the corresponding byte element in the first source operand, If a mask bit is "0"

The register assignment of the implicit third operand is defined to be the architectural register XMM0

128-bit Legacy SSE version: The first source operand and the destination operand is the same. Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged. The mask register operand is implicitly defined to be the architectural register XMM0. An attempt to execute PBLENDVB with a VEX prefix will cause #UD.

VEX.128 encoded version: The first source operand and the destination operand are XMM registers. The second source operand is an XMM register or 128-bit memory location. The mask operand is the third source register, and encoded in bits[7:4] of the immediate byte(imm8). The bits[3:0] of imm8 are ignored. In 32-bit mode, imm8[7] is ignored. The upper bits (VLMAX-1:128) of the corresponding YMM

register (destination register) are zeroed. VEX.L must be 0, otherwise the instruction will #UD. VEX.W must be 0, otherwise, the instruction will #UD.

VPBLENDVB permits the mask to be any XMM or YMM register. In contrast, PBLENDVB treats XMM0 implicitly as the mask and do not support non-destructive destination operation. An attempt to execute PBLENDVB encoded with a VEX prefix will cause a #UD exception.

| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

## Description

Words from the source operand (second operand) are conditionally written to the destination operand (first operand) depending on bits in the immediate operand (third operand). The immediate bits (bits 7:0) form a mask that determines whether the corresponding word in the destination is copied from the source. If a bit in the mask, corresponding to a word, is "1", then the word is copied, else the word is unchanged.

128-bit Legacy SSE version: Bits (VLMAX-1:1288) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

## Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

## Description

Performs a carry-less multiplication of two quadwords, selected from the first source and second source operand according to the value of the immediate byte. Bits 4 and 0 are used to select which 64-bit half of each operand to use according to Table 5-18, other bits of the immediate byte are ignored.

Table 5-18. PCLMULQDQ Quadword Selection of Immediate Byte

| Imm[4] | Imm[0] | PCLMULQDQ Operation                            |
|--------|--------|--|
| 0      | 0      | CL_MUL( SRC2 <sup>1</sup> [63:0], SRC1[63:0] ) |
| 0      | 1      | CL_MUL( SRC2[63:0], SRC1[127:64] )             |
| 1      | 0      | CL_MUL( SRC2[127:64], SRC1[63:0] )             |
| 1      | 1      | CL_MUL( SRC2[127:64], SRC1[127:64] )           |

## NOTES:

1. SRC2 denotes the second source operand, which can be a register or memory; SRC1 denotes the first source and destination operand.

The first source operand and the destination operand are the same and must be an XMM register. The second source operand can be an XMM register or a 128-bit memory location. Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

Compilers and assemblers may implement the following pseudo-op syntax to simply programming and emit the required encoding for Imm8.

Table 5-19. Pseudo-Op and PCLMULQDQ Implementation

| Pseudo-Op                      | Pseudo-Op                             | Imm8 Encoding |

## Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

## Description

Performs a SIMD compare for equality of the packed bytes, words, doublewords, or quadwords in the first source operand and the second source operand. If a pair of data elements is equal, the corresponding data element in the destination operand is set to all 1s; otherwise, it is set to all 0s. The second source operand can be an XMM register or a 128-bit memory location. The first source and destination operands are XMM registers.

The PCMPEQB instruction compares the corresponding bytes in the destination and source operands; the PCMPEQW instruction compares the corresponding words in the destination and source operands; the PCMPEQD instruction compares the corresponding doublewords in the destination and source operands, and the PCMPEQQ instruction compares the corresponding quadwords in the destination and source operands.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

| VEX.128.66.0F3A.WIG 61 /r<br>ib<br>VPCMPESTRI xmm1,<br>xmm2/m128, imm8 | A        | V/V                          | AVX                      | Perform a packed comparison of string data with explicit lengths, generating an index, and storing the result in ECX |

## Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (r) | ModRM:r/m (r) | NA       | NA       |

## Description

The instruction compares data from two strings based on the control encoded in the imm8 byte (as described in *Section 4.1 of Intel 64 and IA-32 Architectures Software Developer's Manual Volume 2B*) generating an index stored to the count register (ECX/RCX). Each string is represented by two values. The first value is an XMM (or possibly m128 for the second operand) which contains the elements of the string (character data). The second value is stored in an input length register. The input length register is specified by EAX/RAX (for xmm1), or EDX/RDX (for xmm2/m128). The length represents the number of Bytes/Words which are valid for the respective xmm/m128 data. The length of each input is interpreted as being the absolute-value of the value north length register. The absolute-value computation saturates to 16 (for bytes) and 8 (for words), based on the value of imm8[bit3] when the value in the length register is greater than 16 (8) or less than -16 (-8).

At this point the comparisons and aggregation described in section *Section 4.1 of Intel 64 and IA-32 Architectures Software Developer's Manual Volume 2B* are performed and the index of the first (or last, according to imm8[6]) set bit of IntRes2 is returned in ECX. If no bits are set in IntRes2, ECX is set to 16 (8).

Note that the Arithmetic Flags are written in a non-standard manner to supply the most relevant information.

CFlag – Reset if IntRes2 is equal to zero, set otherwise

ZFlag – Set if absolute-value of EDX is < 16 (8), reset otherwise

## INSTRUCTION SET REFERENCE

SFlag – Set if absolute-value of EAX is < 16 (8), reset otherwise

| VEX.128.66.0F3A.WIG 60 /r<br>ib<br>VPCMPESTRM xmm1,<br>xmm2/m128, imm8 | A        | V/V                          | AVX                      | Perform a packed comparison of string data with explicit lengths, generating a mask, and storing the result in XMM0 |

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (r) | ModRM:r/m (r) | NA       | NA       |

### Description

The instruction compares data from two strings based on the control encoded in the imm8 byte (as described in *Section 4.1 of Intel 64 and IA-32 Architectures Software Developer's Manual Volume 2A*) generating a mask stored to XMM0. Each string is represented by two values. The first value is an XMM (or possibly m128 for the second operand) which contains the elements of the string (character data). The second value is stored in an input length register. The input length register is specified by EAX/RAX (for xmm1) or EDX/RDX (for xmm2/m128). The length represents the number of Bytes/Words which are valid for the respective xmm/m128 data. The length of each input is interpreted as being the absolute-value of the value in the length register. The absolute-value computation saturates to 16 (for bytes) and 8 (for words), based on the value of imm8[bit3] when the value in the length register is greater than 16 (8) or less than -16 (-8).

At this point the comparisons and aggregation described in *Section 4.1 of Intel 64 and IA-32 Architectures Software Developer's Manual Volume 2B* are performed. As defined by imm8[6], IntRes2 is then either stored to the least significant bits of XMM0 (zero extended to 128 bits) or expanded into a byte/word-mask and then stored to XMM0.

Note that the Arithmetic Flags are written in a non-standard manner to supply the most relevant information

CFlag – Reset if IntRes2 is equal to zero, set otherwise

## INSTRUCTION SET REFERENCE

## Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

## Description

Performs a SIMD signed compare for the greater value of the packed byte, word, doubleword, or quadword integers in the first source operand and the second source operand. If a data element in the first source operand is greater than the corresponding data element in the second source operand, the corresponding data element in the destination operand is set to all 1s; otherwise, it is set to all 0s. The second source operand can be an XMM register or a 128-bit memory location. The first source operand and destination operand are XMM registers.

The PCMPGTB instruction compares the corresponding signed byte integers in the first and second source operands; the PCMPGTW instruction compares the corresponding signed word integers in the first and second source operands; the PCMPGTD instruction compares the corresponding signed doubleword integers in the first and second source operands, and the PCMPGTQ instruction compares the corresponding signed qword integers in the first and second source operands.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

## Operation

COMPARE\_BYTES\_GREATER (SRC1, SRC2)

```
IF SRC1[7:0] > SRC2[7:0]
THEN DEST[7:0] ← FFH;
ELSE DEST[7:0] ← 0; FI;

|---|---------------|---------------|----------|----------|
| A | ModRM:reg (r) | ModRM:r/m (r) | NA       | NA       |

## Description

The instruction compares data from two strings based on the control encoded in the imm8 byte (as described in *Section 3.1.2 of Intel 64 and IA-32 Architectures Software Developer's Manual Volume 2A*) generating an index stored to ECX/RCX. Each string is represented by a single value. The value is an XMM (or possibly m128 for the second operand) which contains the elements of the string (character data). Each input byte/word is augmented with a valid/invalid tag. A byte/word is considered valid only if it has a lower index than the least significant null byte/word. (The least significant null byte/word is also considered invalid.) At this point the comparisons and aggregation described in *Section 3.1.2 of Intel 64 and IA-32 Architectures Software Developer's Manual Volume 2A* are performed and the index of the first (or last, according to imm8[6]) set bit of IntRes2 is returned in ECX. If no bits are set in IntRes2, ECX is set to 16 (8).

Note that the Arithmetic Flags are written in a non-standard manner to supply the most relevant information.

CFlag – Reset if IntRes2 is equal to zero, set otherwise

ZFlag – Set if any byte/word of xmm2/mem128 is null, reset otherwise

SFlag – Set if any byte/word of xmm1 is null, reset otherwise

OFlag –IntRes2[0]

AFlag – Reset

## INSTRUCTION SET REFERENCE

### Description

Permute double-precision floating-point values in the first source operand (second operand) using 8-bit control fields in the low bytes of the second source operand (third operand) and store results in the destination operand (first operand). The first source operand is a YMM register, the second source operand is a YMM register or a 256-bit memory location, and the destination operand is a YMM register.

Figure 5-18. VPERMILPD operation

There is one control byte per destination double-precision element. Each control byte is aligned with the low 8 bits of the corresponding double-precision destination element. Each control byte contains a 1-bit select field (see Figure 5-19) that determines which of the source elements are selected. Source elements are restricted to lie in the same source 128-bit region as the destination.

Figure 5-19. VPERMILPD Shuffle Control

(immediate control version)

Permute double-precision floating-point values in the first source operand (second operand) using two, 1-bit control fields in the low 2 bits of the 8-bit immediate and store results in the destination operand (first operand). The source operand is a YMM register or 256-bit memory location and the destination operand is a YMM register.

Note: For the VEX.128.66.0F3A 05 instruction version, VEX.vvvv is reserved and must be 1111b otherwise instruction will #UD.

Note: For the VEX.256.66.0F3A 05 instruction version, VEX.vvvv is reserved and must be 1111b otherwise instruction will #UD.

## Operation

### Description

(variable control version)

Permute single-precision floating-point values in the first source operand (second operand) using 8-bit control fields in the low bytes of corresponding elements the shuffle control (third operand) and store results in the destination operand (first operand). The first source operand is a YMM register, the second source operand is a YMM register or a 256-bit memory location, and the destination operand is a YMM register.

Figure 5-20. VPERMILPS Operation

There is one control byte per destination single-precision element. Each control byte is aligned with the low 8 bits of the corresponding single-precision destination element. Each control byte contains a 2-bit select field (see Figure 5-21) that determines which of the source elements are selected. Source elements are restricted to lie in the same source 128-bit region as the destination.

Figure 5-21. VPERMILPS Shuffle Control

(immediate control version)

Permute single-precision floating-point values in the first source operand (second operand) using four 2-bit control fields in the 8-bit immediate and store results in the destination operand (first operand). The source operand is a YMM register or 256-bit memory location and the destination operand is a YMM register. This is similar to a wider version of PSHUFD, just operating on single-precision floating-point values.

Note: For the VEX.128.66.0F3A 04 instruction version, VEX.vvvv is reserved and must be 1111b otherwise instruction will #UD.

Note: For the VEX.256.66.0F3A 04 instruction version, VEX.vvvv is reserved and must be 1111b otherwise instruction will #UD.

## Operation

```
Select4(SRC, control) {
CASE (control[1:0]) OF
  0:  TMP ← SRC[31:0];
  1:  TMP ← SRC[63:32];
  2:  TMP ← SRC[95:64];
  3:  TMP ← SRC[127:96];
ESAC;
RETURN TMP
}
```

### Description

Permute 128 bit floating-point-containing fields from the first source operand (second operand) and second source operand (third operand) using bits in the 8-bit immediate and store results in the destination operand (first operand). The first source operand is a YMM register, the second source operand is a YMM register or a 256-bit memory location, and the destination operand is a YMM register.

Figure 5-22. VPERM2F128 Operation

## INSTRUCTION SET REFERENCE

Imm8[1:0] select the source for the first destination 128-bit field, imm8[5:4] select the source for the second destination field. If imm8[3] is set, the low 128-bit field is zeroed. If imm8[7] is set, the high 128-bit field is zeroed.

VEX.L must be 1, otherwise the instruction will #UD.

**NOTES:**

- In 64-bit mode, VEX.W1 is ignored for VPEXTRB/W (similar to legacy REX.W=1 prefix in PEXTRB/W).

**Instruction Operand Encoding**

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:r/m (w) | ModRM:reg (r) | NA       | NA       |
| B | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

**Description**

Extract a byte/word/dword/qword integer value from the source XMM register at a byte/word/dword/qword offset determined from imm8[3:0]. The destination can be a register or byte/word/dword/qword memory location. If the destination is a register, the upper bits of the register are zero extended.

In legacy non-VEX encoded version and if the destination operand is a register, the default operand size in 64-bit mode for PEXTRB/PEXTRW/PEXTRD is 64 bits, the bits above the least significant byte/word/dword data are filled with zeros. PEXTRQ is not encodable in non-64-bit modes and requires REX.W in 64-bit mode.

Note: In VEX.128 encoded versions, VEX.vvvv is reserved and must be 1111b, VEX.L must be 0, otherwise the instruction will #UD. If the destination operand is a register, the default operand size in 64-bit mode for VPEXTRB/VPEXTRW/VPEXTRD is 64 bits, the bits above the least significant byte/word/dword data are filled with zeros. Attempt to execute VPEXTRQ in non-64-bit mode will cause #UD.

## Description

PHADDW adds two adjacent 16-bit signed integers horizontally from the second source operand and the first source operand and packs the 16-bit signed results to the destination operand. PHADDD adds two adjacent 32-bit signed integers horizontally from the second source operand and the first source operand and packs the 32-bit signed results to the destination operand. The first source and destination operands are XMM registers. The second source operand is an XMM register or a 128-bit memory location.

Note that these instructions can operate on either unsigned or signed (two's complement notation) integers; however, it does not set bits in the EFLAGS register to indicate overflow and/or a carry. To prevent undetected overflow conditions, software must control the ranges of the values operated on.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

## Description

PHSUBW performs horizontal subtraction on each adjacent pair of 16-bit signed integers by subtracting the most significant word from the least significant word of each pair in the second source operand and destination operands, and packs the signed 16-bit results to the destination operand. PHSUBD performs horizontal subtraction on each adjacent pair of 32-bit signed integers by subtracting the most significant doubleword from the least significant doubleword of each pair, and packs the signed 32-bit result to the destination operand.

The first source and destination operands are XMM registers. The second source operand is an XMM register or a 128-bit memory location.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

### Description

PHSUBSW performs horizontal subtraction on each adjacent pair of 16-bit signed integers by subtracting the most significant word from the least significant word of each pair in the second source and first source operands. The signed, saturated 16-bit results are packed to the destination operand. The destination and first source operand are XMM registers. The second operand can be an XMM register or a 128-bit memory location.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

## NOTES:

1. In 64-bit mode, VEX.W1 is ignored for VPINSRB/W (similar to legacy REX.W=1 prefix with PIN-SRB/W).

## Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

## Description

Copies a byte/word/dword/qword from the second source operand and inserts it into the destination operand at the byte/word/dword/qword offset specified with the immediate operand (third operand). The other bytes/words/dwords/qwords in the destination register are copied from the first source operand. The byte select is specified by the 4/3/2/1 least-significant bits of the immediate.

The first source operand and destination operands are XMM registers. The second source operand is a r32 register or an 8-/16-/32-bit memory location for byte/word/dword operation. Qword operation is supported only in 64-bit mode, the second operand is a 64-bit register or memory location. REX.W is required to encode PINSRQ in 64-bit mode, PINSRQ is not encodable in non-64-bit modes.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD. Attempt to execute VPINSRQ in non-64-bit mode will cause #UD.

| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

## Description

Multiplies the individual signed words of the first source operand by the corresponding signed words of the second source operand, producing temporary signed, doubleword results. The adjacent doubleword results are then summed and stored in the destination operand. For example, the corresponding low-order words (15:0) and (31-16) in the second source and first source operands are multiplied by one another and the doubleword results are added together and stored in the low doubleword of the destination register (31-0). The same operation is performed on the other pairs of adjacent words. The second source operand is an XMM register or a 128-bit memory location.

The first source and destination operands are XMM registers. The PMADDWD instruction wraps around only in one situation: when the 2 pairs of words being operated on in a group are all 8000H. In this case, the result wraps around to 80000000H.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

PMADDUBSW multiplies vertically each unsigned byte of the first source operand with the corresponding signed byte of the second source operand, producing intermediate signed 16-bit integers. Each adjacent pair of signed words is added and the saturated result is packed to the destination operand. For example, the lowest-order bytes (bits 7:0) in the first source and second source operands are multiplied and the intermediate signed word result is added with the corresponding intermediate result from the 2nd lowest-order bytes (bits 15:8) of the operands; the sign-saturated result is stored in the lowest word of the destination register (15:0). The same operation is performed on the other pairs of adjacent bytes. The second source operand can be an XMM register or 128-bit memory location. The first source operand and destination operands are XMM registers.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

#### Description

Performs a SIMD compare of the packed signed byte, word, or dword integers in the second source operand and the first source operand and returns the maximum value for each pair of integers to the destination operand. The first source and destination operand is an XMM register; The second source operand is an XMM register or a 128-bit memory location.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:1288) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

## Description

Performs a SIMD compare of the packed unsigned byte, word, or dword integers in the second source operand and the first source operand and returns the maximum value for each pair of integers to the destination operand. The first source and destination operand is an XMM register; The second source operand is an XMM register or a 128-bit memory location.

128-bit Legacy SSE version: Bits (255:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (255:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:reg (r) | NA       | NA       |

### Description

Creates a mask made up of the most significant bit of each byte of the source operand (second operand) and stores the result in the low byte or word of the destination operand (first operand). The source operand is an XMM register; the destination operand is a general-purpose register. The byte mask is 16-bits.

The destination operand is a general-purpose register. In 64-bit mode, the default operand size of the destination operand is 64 bits. The upper bits above bit 15 are filled with zeros. REX.W is ignored

VEX.128 encodings are valid but identical in function. VEX.vvvv is reserved and must be 1111b, VEX.L must be 0, otherwise the instruction will #UD.

### Operation

(V)PMOVMSKB instruction with 128-bit source operand and r32:

$r32[0] \leftarrow SRC[7];$

$r32[1] \leftarrow SRC[15];$

(\* Repeat operation for bytes 2 through 14 \*)

$r32[15] \leftarrow SRC[127];$

$r32[31:16] \leftarrow ZERO\_FILL;$

(V)PMOVMSKB instruction with 128-bit source operand and r64:

$r64[0] \leftarrow SRC[7];$

$r64[1] \leftarrow SRC[15];$

(\* Repeat operation for bytes 2 through 14 \*)

$r64[15] \leftarrow \text{SRC}[127];$

$r64[63:16] \leftarrow \text{ZERO\_FILL};$

|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

#### Description

Packed byte, word, or dword integers in the low bytes of the source operand (second operand) are sign extended to word, dword, or quadword integers and stored in packed signed bytes the destination operand.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.vvvv is reserved and must be 1111b, VEX.L must be 0, otherwise the instruction will #UD.

| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Performs a SIMD unsigned multiply of the packed unsigned word integers in the first source operand and the second source operand, and stores the high 16 bits of each 32-bit intermediate results in the destination operand.

The second source operand is an XMM register or a 128-bit memory location. The destination operand and first source operands are XMM registers.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

### Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

PMULHRWSW multiplies vertically each signed 16-bit integer from the first source operand with the corresponding signed 16-bit integer of the second source operand, producing intermediate, signed 32-bit integers. Each intermediate 32-bit integer is truncated to the 18 most significant bits. Rounding is always performed by adding 1 to the least significant bit of the 18-bit intermediate result. The final result is obtained by selecting the 16 bits immediately to the right of the most significant bit of each 18-bit intermediate result and packed to the destination operand. The first source and destination operands are XMM registers. The second source operand is an XMM register or 128-bit memory location.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

## Description

Performs a SIMD signed multiply of the packed signed word (dword) integers in the first source operand and the second source operand and stores the low 16(32) bits of each intermediate 32-bit(64-bit) result in the destination operand. (Figure 4-4 in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B, shows this operation when using 64-bit operands.) The second source operand can be an XMM register or a 128-bit memory location. The first source and destination operands are XMM registers.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Multiplies the first source operand by the second source operand and stores the result in the destination operand. The second source operand is two packed unsigned doubleword integers stored in the first (low) and third doublewords of an XMM register or an 128-bit memory location. The first source operand is two packed doubleword integers stored in the first and third doublewords of an XMM register. The destination contains two packed unsigned quadword integers stored in an XMM register. When a quadword result is too large to be represented in 64 bits (overflow), the result is wrapped around and the low 64 bits are written to the destination element (that is, the carry is ignored).

For 128-bit memory operands, 128 bits are fetched from memory, but only the first and third doublewords are used in the computation.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Shuffles bytes in the first source operand according to the shuffle control mask in the second source operand. The instruction permutes byte data in the first source operand, leaving the shuffle mask unaffected. If the most significant bit (bit[7]) of each byte of the shuffle control mask is set, then constant zero is written in the result byte. Each byte element in the shuffle control mask provides an index field to select the byte element in the first source operand. The index field is defined as the least significant 4 bits of each byte element of the shuffle control mask. The first source and destination operands are XMM registers. The second source operand is either an XMM register or a 128-bit memory location.

128-bit Legacy SSE version: The first source operand and the destination operand are the same. Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: The destination operand is the first operand, the first source operand is the second operand, the second source operand is the third operand. Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise the instruction will #UD.

### Description

Copies doublewords from source operand and inserts them in the destination operand at the locations selected with the immediate control operand. Figure 5-23 shows the operation of the PSHUFD instruction and the encoding of the order operand. Each 2-bit field in the order operand selects the contents of one doubleword location in the destination operand. For example, bits 0 and 1 of the order operand select the contents of doubleword 0 of the destination operand. The encoding of bits 0 and 1 of the order operand (see the field encoding in Figure 5-23) determines which doubleword from the source operand will be copied to doubleword 0 of the destination operand.

Figure 5-23. PSHUFD Instruction Operation

The source operand can be an XMM register or a 128-bit memory location. The destination operand is an XMM register. The order operand is an 8-bit immediate. Note that this instruction permits a doubleword in the source operand to be copied to more than one doubleword location in the destination operand.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:1288) of the destination YMM register are zeroed. VEX.vvvv is reserved and must be 1111b, VEX.L must be 0, otherwise the instruction will #UD.

|---|------------------|---------------|----------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA       | NA       |

## Description

Copies words from the high quadword of the source operand and inserts them in the high quadword of the destination operand at word locations selected with the immediate operand. This operation is similar to the operation used by the PSHUFD instruction, which is illustrated in Figure 4-7 in the Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B. For the PSHUFHW instruction, each 2-bit field in the immediate operand selects the contents of one word location in the high quadword of the destination operand. The binary encodings of the immediate operand fields select words (0, 1, 2 or 3) from the high quadword of the source operand to be copied to the destination operand. The low quadword of the source operand is copied to the low quadword of the destination operand.

The destination operand is an XMM register. The source operand can be an XMM register or a 128-bit memory location. Note that this instruction permits a word in the high quadword of the source operand to be copied to more than one word location in the high quadword of the destination operand.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.vvvv is reserved and must be 1111b, VEX.L must be 0, otherwise the instruction will #UD.

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

## Description

PSIGNB/PSIGNW/PSIGND negates each data element of the first source operand if the signed integer value of the corresponding data element in the second source operand is less than zero. If the signed integer value of a data element in the second source operand is positive, the corresponding data element in the first source operand is unchanged. If a data element in the second source operand is zero, the corresponding data element in the first source operand is set to zero.

PSIGNB operates on signed bytes. PSIGNW operates on 16-bit signed words. PSIGND operates on signed 32-bit integers.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise instructions will #UD.

## Operation

BYTE\_SIGN(SRC1, SRC2)

```

if (SRC2[7..0] < 0 )
    DEST[7...0] ← Neg(SRC1[7...0])
else if (SRC2[7..0] == 0 )
    DEST[7...0] ← 0
else if (SRC2[7..0] > 0 )

| D | VEX.vvvv (w)     | ModRM:r/m (r) | NA            | NA       |

### Description

Shifts the bits in the individual data elements (words, doublewords, or quadword) in the first source operand to the left by the number of bits specified in the count operand. As the bits in the data elements are shifted left, the empty low-order bits are cleared (set to 0). If the value specified by the count operand is greater than 15 (for words), 31 (for doublewords), or 63 (for a quadword), then the destination operand is set to all 0s.

The destination and first source operands are XMM registers. The count operand can be either an XMM register or a 128-bit memory location or an 8-bit immediate. Note that only the first 64-bits of a 128-bit count operand are checked to compute the count.

The PSLLW instruction shifts each of the words in the first source operand to the left by the number of bits specified in the count operand; the PSLLD instruction shifts each of the doublewords in the first source operand; and the PSLLQ instruction shifts the quadword (or quadwords) in the first source operand.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged. If the count operand is a memory address, 128 bits are loaded but the upper 64 bits are ignored.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. For shifts with an immediate count (VEX.128.66.0F 71-73 /6), VEX.vvvv encodes the destination register, and VEX.B + ModRM.r/m encodes the source register. VEX.L must be 0, otherwise instructions will #UD. If the count operand is a memory address, 128 bits are loaded but the upper 64 bits are ignored.

### Operation

## Description

Shifts the bits in the individual data elements (words, doublewords, or quadword) in the first source operand to the right by the number of bits specified in the count operand. As the bits in the data elements are shifted left, the empty high-order bits are filled with the initial value of the sign bit of the data. If the value specified by the count operand is greater than 15 (for words), 31 (for doublewords), or 63 (for a quadword), then the destination operand is filled with the initial value of the sign bit.

The destination and first source operands are XMM registers. The count operand can be either an XMM register or a 128-bit memory location or an 8-bit immediate. Note that only the first 64-bits of a 128-bit count operand are checked to compute the count.

The PSRAW instruction shifts each of the words in the first source operand to the right by the number of bits specified in the count operand; the PSRAD instruction shifts each of the doublewords in the first source operand; and the PSRAQ instruction shifts the quadword (or quadwords) in the first source operand.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged. If the count operand is a memory address, 128 bits are loaded but the upper 64 bits are ignored.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. For shifts with an immediate count (VEX.128.66.0F 71-73 /4), VEX.vvvv encodes the destination register, and VEX.B + ModRM.r/m encodes the source register. VEX.L must be 0, otherwise instructions will #UD. : Bits (255:128) of the corresponding YMM destination register remain unchanged. If the count operand is a memory address, 128 bits are loaded but the upper 64 bits are ignored.

| D | VEX.vvvv (w)     | ModRM:r/m (r) | NA            | NA       |

### Description

Shifts the bits in the individual data elements (words, doublewords, or quadword) in the first source operand to the right by the number of bits specified in the count operand. As the bits in the data elements are shifted right, the empty high-order bits are cleared (set to 0). If the value specified by the count operand is greater than 15 (for words), 31 (for doublewords), or 63 (for a quadword), then the destination operand is set to all 0s.

The destination and first source operands are XMM registers. The count operand can be either an XMM register or a 128-bit memory location or an 8-bit immediate. Note that only the first 64-bits of a 128-bit count operand are checked to compute the count.

The PSRLW instruction shifts each of the words in the first source operand to the right by the number of bits specified in the count operand; the PSRLD instruction shifts each of the doublewords in the first source operand; and the PSRLQ instruction shifts the quadword (or quadwords) in the first source operand.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged. If the count operand is a memory address, 128 bits are loaded but the upper 64 bits are ignored.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. For shifts with an immediate count (VEX.128.66.0F 71-73 /2), VEX.vvvv encodes the destination register, and VEX.B + ModRM.r/m encodes the source register. VEX.L must be 0, otherwise instructions will #UD. If the count operand is a memory address, 128 bits are loaded but the upper 64 bits are ignored.

### Operation

#### **LOGICAL\_RIGHT\_SHIFT\_WORDS(SRC, COUNT\_SRC)**

COUNT  $\leftarrow$  COUNT\_SRC[63:0];

## Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (r) | ModRM:reg (r) | NA       | NA       |

## Description

PTEST and VPTEST set the ZF flag if all bits in the result are 0 of the bitwise AND of the first source operand (first operand) and the second source operand (second

operand). VPTTEST sets the CF flag if all bits in the result are 0 of the bitwise AND of the second source operand (second operand) and the logical NOT of the destination operand.

VTESTPS performs a bitwise comparison of all the sign bits of the packed single-precision elements in the first source operation and corresponding sign bits in the second source operand. If the AND of the source sign bits with the dest sign bits produces all zeros, the ZF is set else the ZF is clear. If the AND of the source sign bits with the inverted dest sign bits produces all zeros the CF is set else the CF is clear. An attempt to execute VTESTPS with VEX.W=1 will cause #UD.

VTESTPD performs a bitwise comparison of all the sign bits of the double-precision elements in the first source operation and corresponding sign bits in the second source operand. If the AND of the source sign bits with the dest sign bits produces all zeros, the ZF is set else the ZF is clear. If the AND the source sign bits with the inverted dest sign bits produces all zeros the CF is set else the CF is clear. An attempt to execute VTESTPS with VEX.W=1 will cause #UD.

The first source register is specified by the ModR/M *reg* field.

VEX.256 encoded version: The first source register is a YMM register. The second source register can be a YMM register or a 256-bit memory location. The destination register is not modified.

128-bit version: The first source register is an XMM register. The second source register can be an XMM register or a 128-bit memory location. The destination register is not modified.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

## Operation

## Description

Subtracts the packed byte, word, doubleword, or quadword integers in the second source operand from the first source operand and stores the result in the destination operand. The second source operand is an XMM register or an 128-bit memory location. The first source operand and destination operands are XMM registers. When a result is too large to be represented in the 8/16/32/64 integer (overflow), the result is wrapped around and the low bits are written to the destination element (that is, the carry is ignored).

Note that these instructions can operate on either unsigned or signed (two's complement notation) integers; however, it does not set bits in the EFLAGS register to indicate overflow and/or a carry. To prevent undetected overflow conditions, software must control the ranges of the values operated on.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise instructions will #UD.

### Instruction Operand Encoding

|   | Operand 1        | Operand2      | Operand3      | Operand4 |
|---|------------------|---------------|---------------|----------|
| A | ModRM:reg (r, w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Performs a SIMD subtract of the packed signed integers of the second source operand from the packed signed integers of the first source operand, and stores the packed integer results in the destination operand. See Figure 9-4 in the Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1, for an illustration of a SIMD operation. Overflow is handled with signed saturation, as described in the following paragraphs.

The first source and destination operands are XMM registers and the second source operand is either an XMM register or a 128-bit memory location.

The PSUBSB instruction subtracts packed signed byte integers. When an individual byte result is beyond the range of a signed byte integer (that is, greater than 7FH or less than 80H), the saturated value of 7FH or 80H, respectively, is written to the destination operand.

The PSUBSW instruction subtracts packed signed word integers. When an individual word result is beyond the range of a signed word integer (that is, greater than 7FFFH or less than 8000H), the saturated value of 7FFFH or 8000H, respectively, is written to the destination operand.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise instructions will #UD.

#### Description

Unpacks and interleaves the high-order data elements (bytes, words, doublewords, and quadwords) of the first source operand and second source operand into the destination operand. (Figure 5-24 shows the unpack operation for bytes in 64-bit operands.). The low-order data elements are ignored.

128-bit Legacy SSE version: The first source operand and the destination operand are the same.

Figure 5-24. PUNPCKHDQ Instruction Operation

The second source operand can be an XMM register or a 128-bit memory location. The first source and destination operands are XMM registers. When the source data comes from a 128-bit memory operand, an implementation may fetch only the appropriate 64 bits; however, alignment to a 16-byte boundary and normal segment checking will still be enforced.

The PUNPCKHBW instruction interleaves the high-order bytes of the source and destination operands, the PUNPCKHWD instruction interleaves the high-order words of the source and destination operands, the PUNPCKHDQ instruction interleaves the high order doubleword (or doublewords) of the source and destination operands, and the PUNPCKHQDQ instruction interleaves the high-order quadwords of the source and destination operands.

128-bit Legacy SSE versions: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded versions: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise instructions will #UD.

#### Description

Unpacks and interleaves the low-order data elements (bytes, words, doublewords, and quadwords) of the first source operand and second source operand into the destination operand. (Figure 5-25 shows the unpack operation for bytes in 64-bit operands.). The high-order data elements are ignored.

128-bit Legacy SSE version: The first source operand and the destination operand are the same.

Figure 5-25. PUNPCKLBW Instruction Operation using 64-bit Operands

The second source operand can be an XMM register or a 128-bit memory location. The first source and destination operands are XMM registers. When the source data comes from a 128-bit memory operand, an implementation may fetch only the appropriate 64 bits; however, alignment to a 16-byte boundary and normal segment checking will still be enforced.

The PUNPCKLBW instruction interleaves the low-order bytes of the source and destination operands, the PUNPCKLWD instruction interleaves the low-order words of the source and destination operands, the PUNPCKLDQ instruction interleaves the low order doubleword (or doublewords) of the source and destination operands, and the PUNPCKLQDQ instruction interleaves the low-order quadwords of the source and destination operands.

128-bit Legacy SSE versions: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded versions: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise instructions will #UD.

## Description

Performs a bitwise logical XOR operation on the second source operand and the first source operand and stores the result in the destination operand. The second source operand is an XMM register or a 128-bit memory location. The first source and destination operands can be XMM registers. Each bit of the result is set to 1 if the corresponding bits of the first and second operands are different; otherwise, each bit is 0 if the corresponding bits of the first and second operand are the same.

128-bit Legacy SSE version: Bits (VLMAX-1:128) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed. VEX.L must be 0, otherwise instructions will #UD.

| VEX.256.0F.WIG 53 /r<br>VRCPPS ymm1, ymm2/m256 | A        | V/V                          | AVX                      | Computes the approximate reciprocals of packed single-precision values in ymm2/mem and stores the results in ymm1 |

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

### Description

Performs an SIMD computation of the approximate reciprocals of the four or eight packed single precision floating-point values in the source operand (second operand) and stores the packed single-precision floating-point results in the destination operand. See Figure 10-5 in the IA-32 Intel Architecture Software Developer's Manual, Volume 1 for an illustration of an SIMD single-precision floating-point operation.

The relative error for this approximation is:

$$|\text{Relative Error}| < 1.5 * 2^{-12}$$

The RCPPS instruction is not affected by the rounding control bits in the MXCSR register.

When a source value is a 0.0, an Inf of the sign of the source value is returned.

A denormal source value is treated as a 0.0 (of the same sign).

Tiny results are always flushed to 0.0, with the sign of the operand:

- The result is guaranteed not to be tiny for inputs that are not greater than  $(2^{125}) * (2 - 3 * 2^{-10})$  in absolute value.
- The result is guaranteed to be flushed to 0 for values greater than  $(2^{126}) * (1 + 3 * 2^{-11})$  in absolute value.
- Input values in between this range may or may not produce tiny results, depending on the implementation.

When a source value is an SNaN or QNaN, the SNaN is converted to a QNaN or the source QNaN is returned.

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

| B | ModRM:reg (w) | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

## Description

Computes of an approximate reciprocal of the low single-precision floating-point value in the second source operand and stores the single-precision floating-point result in the destination operand. The second source operand can be an XMM register or a 32-bit memory location. The first source operand and the destination operand are XMM registers. The three high-order doublewords of the destination operand are copied from the same bits of the first source operand. See Figure 10-6 in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1, for an illustration of a scalar single-precision floating-point operation.

The relative error for this approximation is:

$$|\text{Relative Error}| < 1.5 * 2^{-12}$$

The RCPSS instruction is not affected by the rounding control bits in the MXCSR register. When a source value is a 0.0, an Inf of the sign of the source value is returned.

A denormal source value is treated as a 0.0 (of the same sign).

## INSTRUCTION SET REFERENCE

Tiny results are always flushed to 0.0, with the sign of the operand:

- The result is guaranteed not to be tiny for inputs that are not greater than  $(2^{125}) \cdot (2 - 3 \cdot 2^{-10})$  in absolute value.
- The result is guaranteed to be flushed to 0 for values greater than  $(2^{126}) \cdot (1 + 3 \cdot 2^{-11})$  in absolute value.
- Input values in between this range may or may not produce tiny results, depending on the implementation.

When a source value is an SNaN or QNaN, the SNaN is converted to a QNaN or the source QNaN is returned.

128-bit Legacy SSE version: The first source operand and the destination operand are the same. Bits (VLMAX-1:32) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed.

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

### Description

Performs an SIMD computation of the approximate reciprocals of the square roots of the four or eight packed single precision floating-point values in the source operand (second operand) and stores the packed single-precision floating-point results in the destination operand. See Figure 10-5 in the IA-32 Intel Architecture Software Developer's Manual, Volume 1 for an illustration of an SIMD single-precision floating-point operation.

$$|\text{Relative Error}| < 1.5 * 2^{-12}$$

The RSQRTPS instruction is not affected by the rounding control bits in the MXCSR register.

When a source value is a 0.0, an Inf of the sign of the source value is returned.

A denormal source value is treated as a 0.0 (of the same sign).

When a source value is a negative value (other than 0.0), a floating-point indefinite is returned.

When a source value is an SNaN or QNaN, the SNaN is converted to a QNaN or the source QNaN is returned.

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

| B | ModRM:reg (w) | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Computes an approximate reciprocal of the square root of the low single-precision floating-point value in the second source operand stores the single-precision floating-point result in the destination operand. The second source operand can be an XMM register or a 32-bit memory location. The first source and destination operands are XMM registers. The three high-order doublewords of the destination operand are copied from the same bits of the first source operand. See *Figure 10-6* in the *Intel 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, for an illustration of a scalar single-precision floating point operation. The relative error for this approximation is:

$$|\text{Relative Error}| < 1.5 * 2^{-12}$$

The RSQRTSS instruction is not affected by the rounding control bits in the MXCSR register.

When a source value is a 0.0, an Inf of the sign of the source value is returned.

A denormal source value is treated as a 0.0 (of the same sign).

When a source value is a negative value (other than 0.0), a floating-point indefinite is returned.

When a source value is an SNaN or QNaN, the SNaN is converted to a QNaN or the source QNaN is returned.

128-bit Legacy SSE version: The first source operand and the destination operand are the same. Bits (VLMAX-1:32) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed.

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

### Description

Round the four double-precision floating-point values in the source operand (second operand) by the rounding mode specified in the immediate operand (third operand) and place the result in the destination operand (first operand). The rounding process rounds the input to an integral value and returns the result as a double-precision floating-point value.

The immediate operand specifies control fields for the rounding operation, three bit fields are defined and shown in Figure 5-26. Bit 3 of the immediate byte controls processor behavior for a precision exception, bit 2 selects the source of rounding mode control. Bits 1:0 specify a non-sticky rounding-mode value (Figure 5-26 lists the encoded values for rounding-mode field).

The Precision Floating-Point Exception is signaled according to the immediate operand. If any source operand is an SNaN then it will be converted to a QNaN. If DAZ is set to `1 then denormals will be converted to zero before rounding.

VEX.256 encoded version: The source operand is a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the source operand second source operand or a 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

### Description

Round the DP FP value in the second source operand by the rounding mode specified in the immediate operand and place the result in the destination operand. The rounding process rounds the lowest double precision floating-point input to an integral value and returns the result as a double precision floating-point value in the lowest position. The upper double precision floating-point value in the destination is retained.

The immediate operand specifies control fields for the rounding operation, three bit fields are defined and shown in Figure 5-26. Bit 3 of the immediate byte controls processor behavior for a precision exception, bit 2 selects the source of rounding mode control. Bits 1:0 specify a non-sticky rounding-mode value (Figure 5-26 lists the encoded values for rounding-mode field).

The Precision Floating-Point Exception is signaled according to the immediate operand. If any source operand is an SNaN then it will be converted to a QNaN. If DAZ is set to `1 then denormals will be converted to zero before rounding.

## INSTRUCTION SET REFERENCE

128-bit Legacy SSE version: The first source operand and the destination operand are the same. Bits (VLMAX-1:64) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed.

### Operation

The rounding mode is determined by imm8. Also, upper packed single precision floating-point values (bits[127:32]) from xmm2 are copied to xmm1[127:32]. |

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3      | Operand4 |
|---|---------------|---------------|---------------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA            | NA       |
| B | ModRM:reg (w) | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Round the single precision floating-point value in the second source operand by the rounding mode specified in the immediate operand and place the result in the destination operand. The rounding process rounds the lowest single precision floating-point input to an integral value and returns the result as a single precision floating-point value in the lowest position. The upper three single precision floating-point values in the destination are copied from the first source operand.

The immediate operand specifies control fields for the rounding operation, three bit fields are defined and shown in Figure 5-26. Bit 3 of the immediate byte controls processor behavior for a precision exception, bit 2 selects the source of rounding mode control. Bits 1:0 specify a non-sticky rounding-mode value (Figure 5-26 lists the encoded values for rounding-mode field).

The Precision Floating-Point Exception is signaled according to the immediate operand. If any source operand is an SNaN then it will be converted to a QNaN. If DAZ is set to '1 then denormals will be converted to zero before rounding.

## INSTRUCTION SET REFERENCE

128-bit Legacy SSE version: The first source operand and the destination operand are the same. Bits (VLMAX-1:32) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed.

### Operation

### Description

Moves either of the two packed double-precision floating-point values from each double quadword in the first source operand (second operand) into the low quadword of each double quadword of the destination operand (first operand); moves either of the two packed double-precision floating-point values from the second source operand (third operand) into the high quadword of each double quadword of the destination operand (see Figure 5-27). The immediate determines which values are moved to the destination operand.

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The source can be an XMM register or a 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

## Description

Moves two of the four packed single-precision floating-point values from each double qword of the first source operand (second operand) into the low quadword of each double qword of the destination operand (first operand); moves two of the four packed single-precision floating-point values from each double qword of the second source operand (third operand) into to the high quadword of each double qword of the destination operand (see Figure 5-28). The selector operand (third operand) determines which values are moved to the destination operand.

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

| B | ModRM:reg (w) | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Computes the square root of the low double-precision floating-point value in the second source operand and stores the double-precision floating-point result in the destination operand. The second source operand can be an XMM register or a 64-bit memory location. The first source and destination operands are XMM registers. The high quadword of the destination operand remains unchanged. See Figure 11-4 in the Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1, for an illustration of a scalar double-precision floating-point operation.

128-bit Legacy SSE version: The first source operand and the destination operand are the same. Bits (VLMAX-1:64) of the corresponding YMM destination register remain unchanged.

VEX.128 encoded version: Bits (VLMAX-1:128) of the destination YMM register are zeroed.

### Operation

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (r) | ModRM:r/m (r) | NA       | NA       |

### Description

Performs an unordered compare of the double-precision floating-point values in the low quadwords of operand 1 (first operand) and operand 2 (second operand), and sets the ZF, PF, and CF flags in the EFLAGS register according to the result (unordered, greater than, less than, or equal). The OF, SF and AF flags in the EFLAGS register are set to 0. The unordered result is returned if either source operand is a NaN (QNaN or SNaN).

Operand 1 is an XMM register; operand 2 can be an XMM register or a 64 bit memory location.

The UCOMISD instruction differs from the COMISD instruction in that it signals a SIMD floating-point invalid operation exception (#I) only when a source operand is an SNaN. The COMISD instruction signals an invalid numeric exception only if a source operand is either an SNaN or a QNaN.

The EFLAGS register is not updated if an unmasked SIMD floating-point exception is generated.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

### Operation

**UCOMISD (all versions)**

## UCOMISS - Unordered Compare Scalar Single-Precision Floating-Point Values and Set EFLAGS

| Opcode/<br>Instruction                             | Op<br>En | 64/32 bit<br>Mode<br>Support | CPUID<br>Feature<br>Flag | Description   |
|--|----------|------------------------------|--------------------------|---|
| 0F 2E /r<br>UCOMISS xmm1,<br>xmm2/m32              | A        | V/V                          | SSE                      | Compare low single precision floating-point values in xmm1 and xmm2/mem32 and set the EFLAGS flags accordingly. |
| VEX.LIG.0F.WIG 2E /r<br>VUCOMISS xmm1,<br>xmm2/m32 | A        | V/V                          | AVX                      | Compare low single precision floating-point values in xmm1 and xmm2/mem32 and set the EFLAGS flags accordingly. |

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (r) | ModRM:r/m (r) | NA       | NA       |

### Description

Compares the single-precision floating-point values in the low quadwords of operand 1 (first operand) and operand 2 (second operand), and sets the ZF, PF, and CF flags in the EFLAGS register according to the result (unordered, greater than, less than, or equal). The OF, SF and AF flags in the EFLAGS register are set to 0. The unordered result is returned if either source operand is a NaN (QNaN or SNaN).

Operand 1 is an XMM register; operand 2 can be an XMM register or a 32 bit memory location.

The UCOMISS instruction differs from the COMISS instruction in that it signals a SIMD floating-point invalid operation exception (#1) only if a source operand is an SNaN. The COMISS instruction signals an invalid numeric exception when a source operand is either a QNaN or SNaN.

The EFLAGS register is not updated if an unmasked SIMD floating-point exception is generated.

Note: In VEX-encoded versions, VEX.vvvv is reserved and must be 1111b, otherwise instructions will #UD.

### Operation

| B | ModRM:reg (w)    | VEX.vvvv (r)  | ModRM:r/m (r) | NA       |

### Description

Performs an interleaved unpack of the high double-precision floating-point values from the first source operand and the second source operand. See Figure 4-15 in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B,.

#### 128-bit versions

When unpacking from a memory operand, an implementation may fetch only the appropriate 64 bits; however, alignment to 16-byte boundary and normal segment checking will still be enforced

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: T second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

### Description

Performs a bitwise logical XOR of the four or eight packed single-precision floating-point values from the first source operand and the second source operand, and stores the result in the destination operand

VEX.256 encoded version: The first source operand is a YMM register. The second source operand can be a YMM register or a 256-bit memory location. The destination operand is a YMM register.

VEX.128 encoded version: the first source operand is an XMM register or 128-bit memory location. The destination operand is an XMM register. The upper bits (VLMAX-1:128) of the corresponding YMM register destination are zeroed.

128-bit Legacy SSE version: The second source can be an XMM register or an 128-bit memory location. The destination is not distinct from the first source XMM register and the upper bits (VLMAX-1:128) of the corresponding YMM register destination are unmodified.

|-------|---------------|----------|----------|----------|
| A     | ModRM:r/m (w) | NA       | NA       | NA       |

### Description

The XSAVEOPT instruction paired with XRSTOR is designed to provide a high performance method for system software to perform state save and restore. Refer to Section 3.2.6.1, “XSAVEOPT Usage Guidelines” for the conditions required for use of the instruction.

XSAVEOPT performs a full or partial save of the enabled processor state components to a memory address specified in the destination operand. A full or partial save of the processor states is specified by an implicit mask operand via the register pair, EDX:EAX. The destination operand is a memory location that must be 64-byte aligned. The hardware may optimize the manner in which data is saved. The performance of this instruction will be equal or better than using the XSAVE instruction.

The implicit 64-bit mask operand in EDX:EAX specifies the subset of enabled processor state components to save into the XSAVE/XRSTOR save area. The XSAVE/XRSTOR save area comprises of individual save area for each processor state components and a header section, see Table 3-3.

The bit assignment used for the EDX:EAX register pair matches XCR0 (the XFEATURE\_ENABLED\_MASK register). For the XSAVEOPT instruction, software can specify "1" in any bit position of EDX:EAX, irrespective of whether the corresponding bit position in XCR0 is valid for the processor. The bit vector in EDX:EAX is "anded" with XCR0 to determine which save area will be written. While it's legal to set any bit in the EDX:EAX mask to 1, it is strongly recommended to set only the bits that are required to save/restore specific states. When specifying 1 in any bit position of EDX:EAX mask, software is required to determine the total size of the XSAVE/XRSTOR save area (specified as destination operand) to fit all enabled processor states by using the value enumerated in CPUID.(EAX=0D, ECX=0):EBX.

The content layout of the XSAVE/XRSTOR save area is architecturally defined to be extendable and enumerated via the sub-leaves of CPUID.0DH leaf. The extendable framework of the XSAVE/XRSTOR layout is depicted by Table 3-3. The layout of the XSAVE/XRSTOR save area is fixed and may contain non-contiguous individual save areas. The XSAVE/XRSTOR save area is not compacted if some features are not saved or are not supported by the processor and/or by system software.

The layout of the register fields of first 512 bytes of the XSAVE/XRSTOR is the same as the FXSAVE/FXRSTOR area. But XSAVE/XRSTOR organizes the 512 byte area as x87 FPU states (including FPU operation states, x87/MMX data registers), MXCSR (including MXCSR\_MASK), and XMM registers.

The processor writes 1 or 0 to each.HEADER.XSTATE\_BV[i] bit field of an enabled processor state component in a manner that is consistent to XRSTOR's interaction with HEADER.XSTATE\_BV.

The state updated to the XSAVE/XRSTOR area may be optimized as follows:

- If the state is in its initialized form, the corresponding XSTATE\_BV bit may be set to 0, and the corresponding processor state component that is indicated as initialized will not be saved to memory.

A processor state component save area is not updated if either one of the corresponding bits in the mask operand or in XCR0 is 0. The processor state component that is updated to the save area is computed by bit-wise AND of the mask operand (EDX:EAX) with XCR0.

HEADER.XSTATE\_BV is updated to reflect the data that is actually written to the save area. A "1" bit in the header indicates the contents of the save area corresponding to that bit are valid. A "0" bit in the header indicates that the state corresponding to that bit is in its initialized form. The memory image corresponding to a "0" bit may or may not contain the correct (initialized) value since only the header bit (and not the save area contents) is updated when the header bit value is 0. XRSTOR will ensure the correct value is placed in the register state regardless of the value of the save area when the header bit is zero.

## Operation

```
TMP_MASK[62:0] (EDX[30:0] << 32 ) OR EAX[31:0] ) AND XCR0[62:0];
```

```

### Instruction Operand Encoding

|   | Operand 1        | Operand2     | Operand3      | Operand4 |
|---|------------------|--------------|---------------|----------|
| A | ModRM:reg (r, w) | VEX.vvvv (r) | ModRM:r/m (r) | NA       |

### Description

Performs a set of SIMD multiply-add computation on packed double-precision floating-point values using three source operands and writes the multiply-add results in the destination operand. The destination register operand is also the first source operand. The second operand must be a SIMD register. The third source operand can be a SIMD register or a memory location.

**VFMADD132PD:** Multiplies the two or four packed double-precision floating-point values from the first source operand to the two or four packed double-precision floating-point values in the third source operand, adds the infinite precision intermediate result to the two or four packed double-precision floating-point values in the second source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

**VFMADD213PD:** Multiplies the two or four packed double-precision floating-point values from the second source operand to the two or four packed double-precision floating-point values in the first source operand, adds the infinite precision intermediate result to the two or four packed double-precision floating-point values in the third source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

**VFMADD231PD:** Multiplies the two or four packed double-precision floating-point values from the second source to the two or four packed double-precision floating-point values in the third source operand, adds the infinite precision intermediate result to the two or four packed double-precision floating-point values in the first source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

**VEX.256 encoded version:** The destination operand (also first source operand) is a YMM register and encoded in `reg_field`. The second source operand is a YMM register and encoded in `VEX.vvvv`. The third source operand is a YMM register or a 256-bit memory location and encoded in `rm_field`.

**VEX.128 encoded version:** The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 128-bit memory location and encoded in `rm_field`. The upper 128 bits of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. See also Section 2.3.1, "FMA Instruction Operand Order and Arithmetic Behavior".

## Operation

In the operations below, "+" and "\*" symbols represent multiplication and addition with infinite precision inputs and outputs (no rounding)

### Instruction Operand Encoding

|   | Operand 1        | Operand2     | Operand3      | Operand4 |
|---|------------------|--------------|---------------|----------|
| A | ModRM:reg (r, w) | VEX.vvvv (r) | ModRM:r/m (r) | NA       |

### Description

Performs a set of SIMD multiply-add computation on packed single-precision floating-point values using three source operands and writes the multiply-add results in the destination operand. The destination operand is also the first source operand. The second operand must be a SIMD register. The third source operand can be a SIMD register or a memory location.

**VFMADD132PS:** Multiplies the four or eight packed single-precision floating-point values from the first source operand to the four or eight packed single-precision

floating-point values in the third source operand, adds the infinite precision intermediate result to the four or eight packed single-precision floating-point values in the second source operand, performs rounding and stores the resulting four or eight packed single-precision floating-point values to the destination operand (first source operand).

VFMADD213PS: Multiplies the four or eight packed single-precision floating-point values from the second source operand to the four or eight packed single-precision floating-point values in the first source operand, adds the infinite precision intermediate result to the four or eight packed single-precision floating-point values in the third source operand, performs rounding and stores the resulting the four or eight packed single-precision floating-point values to the destination operand (first source operand).

VFMADD231PS: Multiplies the four or eight packed single-precision floating-point values from the second source operand to the four or eight packed single-precision floating-point values in the third source operand, adds the infinite precision intermediate result to the four or eight packed single-precision floating-point values in the first source operand, performs rounding and stores the resulting four or eight packed single-precision floating-point values to the destination operand (first source operand).

VEX.256 encoded version: The destination operand (also first source operand) is a YMM register and encoded in `reg_field`. The second source operand is a YMM register and encoded in `VEX.vvvv`. The third source operand is a YMM register or a 256-bit memory location and encoded in `rm_field`.

VEX.128 encoded version: The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 128-bit memory location and encoded in `rm_field`. The upper 128 bits of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. |   | Operand 1        | Operand2     | Operand3      | Operand4 |
|---|------------------|--------------|---------------|----------|
| A | ModRM:reg (r, w) | VEX.vvvv (r) | ModRM:r/m (r) | NA       |

### Description

Performs a SIMD multiply-add computation on the low packed double-precision floating-point values using three source operands and writes the multiply-add result in the destination operand. The destination operand is also the first source operand. The second operand must be a SIMD register. The third source operand can be a SIMD register or a memory location.

**VFMADD132SD:** Multiplies the low packed double-precision floating-point value from the first source operand to the low packed double-precision floating-point value in the third source operand, adds the infinite precision intermediate result to the low packed double-precision floating-point values in the second source operand, performs rounding and stores the resulting packed double-precision floating-point value to the destination operand (first source operand).

**VFMADD213SD:** Multiplies the low packed double-precision floating-point value from the second source operand to the low packed double-precision floating-point value in the first source operand, adds the infinite precision intermediate result to the low packed double-precision floating-point value in the third source operand, performs rounding and stores the resulting packed double-precision floating-point value to the destination operand (first source operand).

**VFMADD231SD**: Multiplies the low packed double-precision floating-point value from the second source to the low packed double-precision floating-point value in the third source operand, adds the infinite precision intermediate result to the low packed double-precision floating-point value in the first source operand, performs rounding and stores the resulting packed double-precision floating-point value to the destination operand (first source operand).

VEX.128 encoded version: The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 64-bit memory location and encoded in `rm_field`. The upper bits ([255:128]) of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. See also Section 2.3.1, "FMA Instruction Operand Order and Arithmetic Behavior"

#### Description

VFMADDSUB132PD: Multiplies the two or four packed double-precision floating-point values from the first source operand to the two or four packed double-precision floating-point values in the third source operand. From the infinite precision intermediate result, adds the odd double-precision floating-point elements and subtracts the even double-precision floating-point values in the second source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

VFMADDSUB213PD: Multiplies the two or four packed double-precision floating-point values from the second source operand to the two or four packed double-precision floating-point values in the first source operand. From the infinite precision intermediate result, adds the odd double-precision floating-point elements and subtracts the even double-precision floating-point values in the third source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

VFMADDSUB231PD: Multiplies the two or four packed double-precision floating-point values from the second source operand to the two or four packed double-precision floating-point values in the third source operand. From the infinite precision intermediate result, adds the odd double-precision floating-point elements and subtracts the even double-precision floating-point values in the first source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

VEX.256 encoded version: The destination operand (also first source operand) is a YMM register and encoded in `reg_field`. The second source operand is a YMM register and encoded in `VEX.vvvv`. The third source operand is a YMM register or a 256-bit memory location and encoded in `rm_field`.

VEX.128 encoded version: The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 128-bit memory location and encoded in `rm_field`. The upper 128 bits of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. See also Section 2.3.1, "FMA Instruction Operand Order and Arithmetic Behavior"

#### Description

VFMADDSUB132PS: Multiplies the four or eight packed single-precision floating-point values from the first source operand to the four or eight packed single-precision floating-point values in the third source operand. From the infinite precision intermediate result, adds the odd single-precision floating-point elements and subtracts the even single-precision floating-point values in the second source operand, performs rounding and stores the resulting four or eight packed single-precision floating-point values to the destination operand (first source operand).

VFMADDSUB213PS: Multiplies the four or eight packed single-precision floating-point values from the second source operand to the four or eight packed single-precision floating-point values in the first source operand. From the infinite precision intermediate result, adds the odd single-precision floating-point elements and subtracts the even single-precision floating-point values in the third source operand, performs rounding and stores the resulting four or eight packed single-precision floating-point values to the destination operand (first source operand).

VFMADDSUB231PS: Multiplies the four or eight packed single-precision floating-point values from the second source operand to the four or eight packed single-precision floating-point values in the third source operand. From the infinite precision intermediate result, adds the odd single-precision floating-point elements and subtracts the even single-precision floating-point values in the first source operand, performs rounding and stores the resulting four or eight packed single-precision floating-point values to the destination operand (first source operand).

VEX.256 encoded version: The destination operand (also first source operand) is a YMM register and encoded in `reg_field`. The second source operand is a YMM register and encoded in `VEX.vvvv`. The third source operand is a YMM register or a 256-bit memory location and encoded in `rm_field`.

VEX.128 encoded version: The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 128-bit memory location and encoded in `rm_field`. The upper 128 bits of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. #### Description

**VFMSUBADD132PD:** Multiplies the two or four packed double-precision floating-point values from the first source operand to the two or four packed double-precision floating-point values in the third source operand. From the infinite precision intermediate result, subtracts the odd double-precision floating-point elements and adds the even double-precision floating-point values in the second source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

**VFMSUBADD213PD:** Multiplies the two or four packed double-precision floating-point values from the second source operand to the two or four packed double-precision floating-point values in the first source operand. From the infinite precision intermediate result, subtracts the odd double-precision floating-point elements and adds the even double-precision floating-point values in the third source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

**VFMSUBADD231PD:** Multiplies the two or four packed double-precision floating-point values from the second source operand to the two or four packed double-precision floating-point values in the third source operand. From the infinite precision intermediate result, subtracts the odd double-precision floating-point elements and adds the even double-precision floating-point values in the first source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

**VEX.256 encoded version:** The destination operand (also first source operand) is a YMM register and encoded in `reg_field`. The second source operand is a YMM register and encoded in `VEX.vvvv`. The third source operand is a YMM register or a 256-bit memory location and encoded in `rm_field`.

**VEX.128 encoded version:** The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 128-bit memory location and encoded in `rm_field`. The upper 128 bits of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. #### Description

**VFMSUBADD132PS:** Multiplies the four or eight packed single-precision floating-point values from the first source operand to the four or eight packed single-precision floating-point values in the third source operand. From the infinite precision intermediate result, subtracts the odd single-precision floating-point elements and adds the even single-precision floating-point values in the second source operand, performs rounding and stores the resulting four or eight packed single-precision floating-point values to the destination operand (first source operand).

**VFMSUBADD213PS:** Multiplies the four or eight packed single-precision floating-point values from the second source operand to the four or eight packed single-precision floating-point values in the first source operand. From the infinite precision intermediate result, subtracts the odd single-precision floating-point elements and adds the even single-precision floating-point values in the third source operand, performs rounding and stores the resulting four or eight packed single-precision floating-point values to the destination operand (first source operand).

**VFMSUBADD231PS:** Multiplies the four or eight packed single-precision floating-point values from the second source operand to the four or eight packed single-precision floating-point values in the third source operand. From the infinite precision intermediate result, subtracts the odd single-precision floating-point elements and adds the even single-precision floating-point values in the first source operand, performs rounding and stores the resulting four or eight packed single-precision floating-point values to the destination operand (first source operand).

**VEX.256 encoded version:** The destination operand (also first source operand) is a YMM register and encoded in `reg_field`. The second source operand is a YMM register and encoded in `VEX.vvvv`. The third source operand is a YMM register or a 256-bit memory location and encoded in `rm_field`.

**VEX.128 encoded version:** The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 128-bit memory location and encoded in `rm_field`. The upper 128 bits of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. See also Section 2.3.1, "FMA Instruction Operand Order and Arithmetic Behavior".

|---|------------------|--------------|---------------|----------|
| A | ModRM:reg (r, w) | VEX.vvvv (r) | ModRM:r/m (r) | NA       |

### Description

Performs a set of SIMD multiply-subtract computation on packed double-precision floating-point values using three source operands and writes the multiply-subtract results in the destination operand. The destination operand is also the first source operand. The second operand must be a SIMD register. The third source operand can be a SIMD register or a memory location.

**VFMSUB132PD:** Multiplies the two or four packed double-precision floating-point values from the first source operand to the two or four packed double-precision floating-point values in the second source operand. From the infinite precision intermediate result, subtracts the two or four packed double-precision floating-point values in the second source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

**VFMSUB213PD:** Multiplies the two or four packed double-precision floating-point values from the second source operand to the two or four packed double-precision floating-point values in the first source operand. From the infinite precision intermediate result, subtracts the two or four packed double-precision floating-point values in the third source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

**VFMSUB231PD:** Multiplies the two or four packed double-precision floating-point values from the second source to the two or four packed double-precision floating-point values in the third source operand. From the infinite precision intermediate result, subtracts the two or four packed double-precision floating-point values in the first source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).  
**VEX.256 encoded version:** The destination operand (also first source operand) is a YMM register and encoded in `reg_field`. The second source operand is a YMM register and encoded in `VEX.vvvv`. The third source operand is a YMM register or a 256-bit memory location and encoded in `rm_field`.

**VEX.128 encoded version:** The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 128-bit memory location and encoded in `rm_field`. The upper 128 bits of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. See also Section 2.3.1, "FMA Instruction Operand Order and Arithmetic Behavior"

### Instruction Operand Encoding

|   | Operand 1        | Operand2     | Operand3      | Operand4 |
|---|------------------|--------------|---------------|----------|
| A | ModRM:reg (r, w) | VEX.vvvv (r) | ModRM:r/m (r) | NA       |

### Description

Performs a SIMD multiply-subtract computation on the low packed double-precision floating-point values using three source operands and writes the multiply-add result in the destination operand. The destination operand is also the first source operand. The second operand must be a SIMD register. The third source operand can be a SIMD register or a memory location.

**VFMSUB132SD:** Multiplies the low packed double-precision floating-point value from the first source operand to the low packed double-precision floating-point value in the third source operand. From the infinite precision intermediate result, subtracts the low packed double-precision floating-point values in the second source operand, performs rounding and stores the resulting packed double-precision floating-point value to the destination operand (first source operand).

**VFMSUB213SD:** Multiplies the low packed double-precision floating-point value from the second source operand to the low packed double-precision floating-point value in the first source operand. From the infinite precision intermediate result, subtracts the low packed double-precision floating-point value in the third source operand, performs rounding and stores the resulting packed double-precision floating-point value to the destination operand (first source operand).

**VFMSUB231SD:** Multiplies the low packed double-precision floating-point value from the second source to the low packed double-precision floating-point value in the third source operand. From the infinite precision intermediate result, subtracts the low packed double-precision floating-point value in the first source operand, performs rounding and stores the resulting packed double-precision floating-point value to the destination operand (first source operand).

VEX.128 encoded version: The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 64-bit memory location and encoded in `rm_field`. The upper bits ([255:128]) of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. See also Section 2.3.1, "FMA Instruction Operand Order and Arithmetic Behavior".

### Description

VFNMADD132PD: Multiplies the two or four packed double-precision floating-point values from the first source operand to the two or four packed double-precision

floating-point values in the third source operand, adds the negated infinite precision intermediate result to the two or four packed double-precision floating-point values in the second source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

**VFNMADD213PD:** Multiplies the two or four packed double-precision floating-point values from the second source operand to the two or four packed double-precision floating-point values in the first source operand, adds the negated infinite precision intermediate result to the two or four packed double-precision floating-point values in the third source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

**VFNMADD231PD:** Multiplies the two or four packed double-precision floating-point values from the second source to the two or four packed double-precision floating-point values in the third source operand, adds the negated infinite precision intermediate result to the two or four packed double-precision floating-point values in the first source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

**VEX.256 encoded version:** The destination operand (also first source operand) is a YMM register and encoded in `reg_field`. The second source operand is a YMM register and encoded in `VEX.vvvv`. The third source operand is a YMM register or a 256-bit memory location and encoded in `rm_field`.

**VEX.128 encoded version:** The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 128-bit memory location and encoded in `rm_field`. The upper 128 bits of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. See also Section 2.3.1, "FMA Instruction Operand Order and Arithmetic Behavior".

### Description

VFMADD132PS: Multiplies the four or eight packed single-precision floating-point values from the first source operand to the four or eight packed single-precision

floating-point values in the third source operand, adds the negated infinite precision intermediate result to the four or eight packed single-precision floating-point values in the second source operand, performs rounding and stores the resulting four or eight packed single-precision floating-point values to the destination operand (first source operand).

**VFMADD213PS:** Multiplies the four or eight packed single-precision floating-point values from the second source operand to the four or eight packed single-precision floating-point values in the first source operand, adds the negated infinite precision intermediate result to the four or eight packed single-precision floating-point values in the third source operand, performs rounding and stores the resulting the four or eight packed single-precision floating-point values to the destination operand (first source operand).

**VFMADD231PS:** Multiplies the four or eight packed single-precision floating-point values from the second source operand to the four or eight packed single-precision floating-point values in the third source operand, adds the negated infinite precision intermediate result to the four or eight packed single-precision floating-point values in the first source operand, performs rounding and stores the resulting four or eight packed single-precision floating-point values to the destination operand (first source operand).

**VEX.256 encoded version:** The destination operand (also first source operand) is a YMM register and encoded in `reg_field`. The second source operand is a YMM register and encoded in `VEX.vvvv`. The third source operand is a YMM register or a 256-bit memory location and encoded in `rm_field`.

**VEX.128 encoded version:** The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 128-bit memory location and encoded in `rm_field`. The upper 128 bits of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. See also Section 2.3.1, "FMA Instruction Operand Order and Arithmetic Behavior".

### Instruction Operand Encoding

|   | Operand 1        | Operand2     | Operand3      | Operand4 |
|---|------------------|--------------|---------------|----------|
| A | ModRM:reg (r, w) | VEX.vvvv (r) | ModRM:r/m (r) | NA       |

### Description

**VFMADD132SD:** Multiplies the low packed double-precision floating-point value from the first source operand to the low packed double-precision floating-point value in the third source operand, adds the negated infinite precision intermediate result to the low packed double-precision floating-point values in the second source operand, performs rounding and stores the resulting packed double-precision floating-point value to the destination operand (first source operand).

**VFMADD213SD:** Multiplies the low packed double-precision floating-point value from the second source operand to the low packed double-precision floating-point value in the first source operand, adds the negated infinite precision intermediate result to the low packed double-precision floating-point value in the third source operand, performs rounding and stores the resulting packed double-precision floating-point value to the destination operand (first source operand).

**VFMADD231SD:** Multiplies the low packed double-precision floating-point value from the second source to the low packed double-precision floating-point value in the third source operand, adds the negated infinite precision intermediate result to the low packed double-precision floating-point value in the first source operand,

performs rounding and stores the resulting packed double-precision floating-point value to the destination operand (first source operand).

VEX.128 encoded version: The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 64-bit memory location and encoded in `rm_field`. The upper bits ([255:128]) of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. See also Section 2.3.1, "FMA Instruction Operand Order and Arithmetic Behavior".

## Description

**VFNSUB132PD:** Multiplies the two or four packed double-precision floating-point values from the first source operand to the two or four packed double-precision floating-point values in the third source operand. From negated infinite precision intermediate results, subtracts the two or four packed double-precision floating-point values in the second source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

**VFMSUB213PD:** Multiplies the two or four packed double-precision floating-point values from the second source operand to the two or four packed double-precision floating-point values in the first source operand. From negated infinite precision intermediate results, subtracts the two or four packed double-precision floating-point values in the third source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand).

**VFMSUB231PD:** Multiplies the two or four packed double-precision floating-point values from the second source to the two or four packed double-precision floating-point values in the third source operand. From negated infinite precision intermediate results, subtracts the two or four packed double-precision floating-point values in the first source operand, performs rounding and stores the resulting two or four packed double-precision floating-point values to the destination operand (first source operand). VEX.256 encoded version: The destination operand (also first source operand) is a YMM register and encoded in `reg_field`. The second source operand is a YMM register and encoded in `VEX.vvvv`. The third source operand is a YMM register or a 256-bit memory location and encoded in `rm_field`.

VEX.128 encoded version: The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 128-bit memory location and encoded in `rm_field`. The upper 128 bits of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. See also Section 2.3.1, "FMA Instruction Operand Order and Arithmetic

Behavior”.

### Instruction Operand Encoding

|   | Operand 1        | Operand2     | Operand3      | Operand4 |
|---|------------------|--------------|---------------|----------|
| A | ModRM:reg (r, w) | VEX.vvvv (r) | ModRM:r/m (r) | NA       |

### Description

**VFNMSUB132SD:** Multiplies the low packed double-precision floating-point value from the first source operand to the low packed double-precision floating-point value in the third source operand. From negated infinite precision intermediate result, subtracts the low double-precision floating-point value in the second source operand, performs rounding and stores the resulting packed double-precision floating-point value to the destination operand (first source operand).

**VFNMSUB213SD:** Multiplies the low packed double-precision floating-point value from the second source operand to the low packed double-precision floating-point value in the first source operand. From negated infinite precision intermediate result, subtracts the low double-precision floating-point value in the third source operand, performs rounding and stores the resulting packed double-precision floating-point value to the destination operand (first source operand).

**VFNMSUB231SD:** Multiplies the low packed double-precision floating-point value from the second source to the low packed double-precision floating-point value in the third source operand. From negated infinite precision intermediate result, subtracts

the low double-precision floating-point value in the first source operand, performs rounding and stores the resulting packed double-precision floating-point value to the destination operand (first source operand).

VEX.128 encoded version: The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 64-bit memory location and encoded in `rm_field`. The upper bits ([255:128]) of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. See also Section 2.3.1, "FMA Instruction Operand Order and Arithmetic Behavior".

### Operation

In the operations below, “-” and “\*” symbols represent multiplication and addition with infinite precision inputs and outputs (no rounding)

### Instruction Operand Encoding

|   | Operand 1        | Operand2     | Operand3      | Operand4 |
|---|------------------|--------------|---------------|----------|
| A | ModRM:reg (r, w) | VEX.vvvv (r) | ModRM:r/m (r) | NA       |

### Description

**VFNMSSUB132SS:** Multiplies the low packed single-precision floating-point value from the first source operand to the low packed single-precision floating-point value in the third source operand. From negated infinite precision intermediate result, the low single-precision floating-point value in the second source operand, performs rounding and stores the resulting packed single-precision floating-point value to the destination operand (first source operand).

**VFNMSUB213SS:** Multiplies the low packed single-precision floating-point value from the second source operand to the low packed single-precision floating-point value in the first source operand. From negated infinite precision intermediate result, the low single-precision floating-point value in the third source operand, performs rounding and stores the resulting packed single-precision floating-point value to the destination operand (first source operand).

**VFNMSUB231SS:** Multiplies the low packed single-precision floating-point value from the second source to the low packed single-precision floating-point value in the third source operand. From negated infinite precision intermediate result, the low single-

precision floating-point value in the first source operand, performs rounding and stores the resulting packed single-precision floating-point value to the destination operand (first source operand).

VEX.128 encoded version: The destination operand (also first source operand) is a XMM register and encoded in `reg_field`. The second source operand is a XMM register and encoded in `VEX.vvvv`. The third source operand is a XMM register or a 32-bit memory location and encoded in `rm_field`. The upper bits ([255:128]) of the YMM destination register are zeroed.

Compiler tools may optionally support a complementary mnemonic for each instruction mnemonic listed in the opcode/instruction column of the summary table. The behavior of the complementary mnemonic in situations involving NaNs are governed by the definition of the instruction mnemonic defined in the opcode/instruction column. See also Section 2.3.1, "FMA Instruction Operand Order and Arithmetic Behavior".

# CHAPTER 7

## POST-32NM PROCESSOR INSTRUCTIONS

---

### 7.1 OVERVIEW

This chapter describes additional instructions targeted for Intel 64 architecture processors in process technology smaller than 32 nm. These instructions include

- Two instructions are added to support 16-bit floating-point data type conversion to and from single-precision floating-point type. Conversion to packed 16-bit floating-point values from packed single-precision floating-point values also provides rounding control using an immediate byte. These float-16 instructions converts packed data types of different sizes following the same manner as the 256-bit vector SIMD extension, AVX.
- One instruction that generates random numbers of 16/32/64 bit wide random integers. The random number generator instruction operates on general-purpose registers.
- Four instructions that allow software working in 64-bit environment to read and write FS base and GS base registers in all privileged levels.

### 7.2 CPUID DETECTION OF NEW INSTRUCTIONS

Application using float 16 instruction must follow a detection sequence similar to AVX to ensure:

- The OS has enabled YMM state management support,
- The processor support AVX as indicated by the CPUID feature flag, i.e. CPUID.01H:ECX.AVX[bit 28] = 1.
- The processor support 16-bit floating-point conversion instructions via a CPUID feature flag (CPUID.01H:ECX.F16C[bit 29] = 1).

Application detection of Float-16 conversion instructions follow the general procedural flow in Figure 7-1.

Figure 7-1. General Procedural Flow of Application Detection of Float-16

---

INT supports\_f16c()

```

{ ; result in eax
  mov eax, 1
  cpuid
  and ecx, 038000000H
  cmp ecx, 038000000H; check OSXSAVE, AVX, F16C feature flags
  jne not_supported
  ; processor supports AVX,F16C instructions and XGETBV is enabled by OS
  mov ecx, 0; specify 0 for XFEATURE_ENABLED_MASK register
  XGETBV; result in EDX:EAX
  and eax, 06H
  cmp eax, 06H; check OS has enabled both XMM and YMM state support
  jne not_supported
  mov eax, 1
  jmp done
NOT_SUPPORTED:
  mov eax, 0
done:
  
```

}

RDRAND, RDFSBASE/RDGSBASE, WRFSBASE/WRGSBASE operates on general purpose registers only.

Before software attempts to use the RDRAND instruction, it must check that the CPUID feature flag indicating processor supports RDRAND, i.e. if CPUID.01H:ECX.RDRAND[bit 30] = 1.

CPUID.(EAX=07H, ECX=0H):EBX.FSGSBASE[bit 0] = 1 indicates availability of instructions that are primarily targeting use by system software manipulating the base of FS and GS segments. These instructions require enabling by OS (see Section 7.5). An OS may provide programming interfaces indicating its support of application use of RDFSBASE/RDGSBASE, WRFSBASE/WRGSBASE instructions.

## 7.3 16-BIT FLOATING-POINT DATA TYPE SUPPORT

Two new instructions support half-precision floating-point data type with conversion to and from single-precision floating-point data types. Table 7-1 gives the length, precision, and approximate normalized range that can be represented by half and single precision data types. Denormal values are also supported in these types.

**Table 7-1. Length, Precision, and Range of Floating-Point Data Types**

| Data Type        | Length | Precision (Bits) | Approximate Normalized Range |   |
|------------------|--------|------------------|------------------------------|---|
|                  |        |                  | Binary                       | Decimal   |
| Half Precision   | 16     | 11               | $2^{-14}$ to $2^{15}$        | $3.1 \times 10^{-5}$ to $6.50 \times 10^4$        |
| Single Precision | 32     | 24               | $2^{-126}$ to $2^{127}$      | $1.18 \times 10^{-38}$ to $3.40 \times 10^{38}$   |
| Double Precision | 64     | 53               | $2^{-1022}$ to $2^{1023}$    | $2.23 \times 10^{-308}$ to $1.79 \times 10^{308}$ |

Table 7-2 shows the floating-point encodings for zeros, denormalized finite numbers, normalized finite numbers, infinities, and NaNs for each of the three floating-point data types.

**Table 7-2. Half-Precision Floating-Point Number and NaN Encodings**

| Class    |                                      | Sign   | Biased Exponent | Significand          |                     |

|          |                                      |        | ← 5Bits →       |                      | ← 10 Bits →         |
|          |                                      |        | ← 8 Bits →      |                      | ← 23Bits →          |
|          |                                      |        | ← 11 Bits →     |                      | ← 52Bits →          |

**NOTES:**

1. Integer bit is implied and not stored in memory format.
2. The fraction for SNaN encodings must be non-zero with the most-significant bit 0.
3. The most-significant bit of the fraction for QNaN encoding must be 1.

Half-precision floating-point data type consists of a sign bit, a 5-bit exponent field, and a 11-bit significand field. The 11-bit significand consists of an implied integer bit that is not stored and a 10-bit fraction field that is stored as the 10 least-significant bits along with the sign bit (bit 15) and the exponent field (bits 14:10), see Figure 7-2.

Figure 7-2. Floating-Point Data Types

The exponent of each floating-point data type is encoded in biased format, the bias constant is 15 for half-precision floating-point data type. When storing floating-point values in memory, half-precision values are stored in 2 consecutive bytes in memory. Table 7-3 shows how the real number 178.125 (in ordinary decimal format) is stored in IEEE Standard 754 floating-point format. The table lists a progression of real number notations that leads to the half-precision, 16-bit floating-point format.

Table 7-3. Real and Floating-Point Number Notation

| Notation                            | Value                            |                 |                            |
|-------------------------------------|----------------------------------|-----------------|----------------------------|
| Ordinary Decimal                    | 178.125                          |                 |                            |
| Scientific Decimal                  | 1.78125E <sub>10</sub> 2         |                 |                            |

|                                     | 0                                | 10110           | 0110010001<br>1. (Implied) |

### 7.3.1 Half-Precision Floating-Point Conversion

Half-precision floating-point values are not used by the processor directly for arithmetic operations. Two instructions, *VCVTPH2PS*, *VCVTPS2PH*, provide conversion between half-precision and single-precision floating-point values.

The conversion operations of *VCVTPS2PH* allow programmer to specify rounding control using control fields in an immediate byte. The effect of the immediate byte are listed in Table 7-4.

Rounding control can use *Imm[2]* to select an override RC field specified in *Imm[1:0]* or use *MXCSR* setting.

**Table 7-4. Immediate Byte Encoding for 16-bit Floating-Point Conversion Instructions**

| Bits     | Field Name/value | Description               | Comment         |
|----------|------------------|---------------------------|-----------------|
| Imm[1:0] | RC=00B           | Round to nearest even     | If Imm[2] = 0   |
|          | RC=01B           | Round down                |                 |
|          | RC=10B           | Round up                  |                 |
|          | RC=11B           | Truncate                  |                 |
| Imm[2]   | MS1=0            | Use imm[1:0] for rounding | Ignore MXCSR.RC |
|          | MS1=1            | Use MXCSR.RC for rounding |                 |
| Imm[7:3] | Ignored          | Ignored by processor      |                 |

*VCVTPH2PS* and *VCVTPS2PH* are subject to SIMD floating-point exceptions. Specifically, they can cause invalid operation exception (see Table 7-6), the result of which is shown in Table 7-5.

**Table 7-5. Non-Numerical Behavior for *VCVTPH2PS*, *VCVTPS2PH***

| Source Operands | Masked Result     | Unmasked Result                      |
|-----------------|-------------------|--------------------------------------|
| QNaN            | QNaN <sup>1</sup> | QNaN <sup>1</sup> (not an exception) |
| SNaN            | QNaN <sup>2</sup> | None                                 |

**NOTES:**

1. The half precision output QNaN<sup>1</sup> is created from the single precision input QNaN as follows: the sign bit is preserved, the 8-bit exponent FFH is replaced by the 5-bit exponent 1FH, and the 24-bit significand is truncated to an 11-bit significand by removing its 14 least significant bits.

- The half precision output QNaN1 is created from the single precision input SNaN as follows: the sign bit is preserved, the 8-bit exponent FFH is replaced by the 5-bit exponent 1FH, and the 24-bit significand is truncated to an 11-bit significand by removing its 14 least significant bits. The second most significant bit of the significand is changed from 0 to 1 to convert the signaling NaN into a quiet NaN.

**Table 7-6. Invalid Operation for VCVTPH2PS, VCVTPS2PH**

| Instruction | Condition | Masked Result | Unmasked Result |
|-------------|-----------|---------------|-----------------|
| VCVTPH2PS   | SRC = NaN | See Table 7-5 | #I=1            |
| VCVTPS2PH   | SRC = NaN | See Table 7-5 | #I=1            |

VCVTPS2PH can cause denormal exceptions if the value of the source operand is denormal relative to the numerical range represented by the source format (see Table 7-7).

**Table 7-7. Denormal Condition for VCVTPS2PH**

| Instruction | Condition   | Masked Result <sup>1</sup>  | Unmasked Result        |
|-------------|---|---|------------------------|
| VCVTPH2PS   | SRC is denormal relative to input format <sup>1</sup> | res = Result rounded to the destination precision and using the bounded exponent, but only if no unmasked post-computation exception occurs.<br>#DE unchanged | Same as masked result. |
| VCVTPS2PH   | SRC is denormal relative to input format <sup>1</sup> | res = Result rounded to the destination precision and using the bounded exponent, but only if no unmasked post-computation exception occurs.<br>#DE=1         | #DE=1                  |

**NOTES:**

- Masked and unmasked result is shown in Table 7-7.

VCVTPS2PH can cause an underflow exception if the result of the conversion is less than the underflow threshold for half-precision floating-point data type , i.e.  $|x| < 1.0 * 2^{-14}$ .

**Table 7-8. Underflow Condition for VCVTPS2PH**

| Instruction | Condition | Masked Result <sup>1</sup> | Unmasked Result |
|-------------|-----------|----------------------------|-----------------|
|-------------|-----------|----------------------------|-----------------|

**Table 7-8. Underflow Condition for VCVTSP2PH**

|           |   |   |   |
|-----------|---|---|---|
| VCVTSP2PH | Result < smallest destination precision final normal value <sup>2</sup> | Result = +0 or -0, denormal, normal.<br>#UE = 1.<br>#PE = 1 if the result is inexact. | #UE=1,<br>#PE = 1 if the result is inexact. |
|-----------|---|---|---|

**NOTES:**

1. Masked and unmasked result is shown in Table 7-7.
2. If FTZ is not set ( MXCSR.FTZ = 1 ), masked and unmasked result is shown in Table 7-8. If FTZ is set (MXCSR.FTZ = 1), inexact result = +0 or - 0, #PE and #UE are reported.

VCVTSP2PH can cause an overflow exception if the result of the conversion is greater than the maximum representable value for half-precision floating-point data type, i.e.  $|x| \geq 1.0 * 2^{16}$ .

**Table 7-9. Overflow Condition for VCVTSP2PH**

| Instruction | Condition  | Masked Result                    | Unmasked Result |
|-------------|--|----------------------------------|-----------------|
| VCVTSP2PH   | Result ≥ largest destination precision final normal value <sup>1</sup> | Result = +Inf or -Inf.<br>#OE=1. | #OE=1.          |

VCVTSP2PH can cause an inexact exception if the result of the conversion is not exactly representable in the destination format.

**Table 7-10. Inexact Condition for VCVTSP2PH**

| Instruction | Condition   | Masked Result <sup>1</sup>   | Unmasked Result  |
|-------------|---|--|--|
| VCVTSP2PH   | The result is not representable in the destination format | res = Result rounded to the destination precision and using the bounded exponent, but only if no unmasked underflow or overflow conditions occur (this exception can occur in the presence of a masked underflow or overflow).<br>#PE=1. | Only if no underflow/overflow condition occurred, or if the corresponding exceptions are masked: <ul style="list-style-type: none"> <li>▪ Set #OE if masked overflow and set result as described above for masked overflow.</li> <li>▪ Set #UE if masked underflow and set result as described above for masked underflow.</li> </ul> If neither underflow nor overflow, result equals the result rounded to the destination precision and using the bounded exponent set #PE = 1. |

## NOTES:

1. If a source is denormal relative to input format with DM masked and at least one of PM or UM unmasked, then an exception will be raised with DE, UE and PE set.

## 7.4 VECTOR INSTRUCTION EXCEPTION SPECIFICATION

The exception behavior of instructions operating on YMM states follows the updated classification table of Table 7-11. The instructions VCVTQ2PH and VCVTQ2PH are described by type 11.

**Table 7-11. Exception class description**

| Exception Class | NI Family                | Mem arg  | Floating Point Exceptions (#XM) |
|-----------------|--------------------------|--|---------------------------------|
| Type 1          | AVX,<br>Legacy SSE       | 16/32 byte<br>explicitly aligned   | none                            |
| Type 2          | AVX, FMA,<br>Legacy SSE  | 16/32 byte; not<br>explicitly aligned<br>with VEX prefix;<br>explicitly aligned<br>without VEX | yes                             |
| Type 3          | AVX, FMA,,<br>Legacy SSE | < 16 byte  | yes                             |
| Type 4          | AVX,<br>Legacy SSE       | 16/32 byte not<br>explicitly aligned<br>with VEX prefix;<br>explicitly aligned<br>without VEX  | no                              |
| Type 5          | AVX,<br>Legacy SSE       | < 16 byte  | no                              |
| Type 6          | AVX (no Legacy<br>SSE)   | Varies   | (At present,<br>none do)        |
| Type 7          | AVX,<br>Legacy SSE       | none   | none                            |
| Type 8          | AVX                      | none   | none                            |
| Type 9          | AVX                      | 4 byte   | none                            |
| Type 10         | AVX, Legacy SSE          | 16/32 byte; not<br>explicitly aligned  | no                              |
| Type 11         | AVX                      | Not explicitly<br>aligned, no AC#  | yes                             |

### 7.4.1 Exception Type 11 (VEX-only, mem arg no AC, floating-point exceptions)

| Exception                          | Real | Virtual 80x86 | Protected and Compatibility | 64-bit | Cause of Exception  |
|------------------------------------|------|---------------|-----------------------------|--------|---|
| Invalid Opcode, #UD                | X    | X             |                             |        | VEX prefix  |
|                                    |      |               | X                           | X      | VEX prefix:<br>If XFEATURE_ENABLED_MASK[2:1] != '11b'.<br>If CR4.OSXSAVE[bit 18]=0.   |
|                                    | X    | X             | X                           | X      | If preceded by a LOCK prefix (FOH)  |
|                                    |      |               | X                           | X      | If any REX, F2, F3, or 66 prefixes precede a VEX prefix                               |
|                                    | X    | X             | X                           | X      | If any corresponding CPUID feature flag is '0'  |
| Device Not Available, #NM          | X    | X             | X                           | X      | If CR0.TS[bit 3]=1  |
| Stack, SS(0)                       |      |               | X                           |        | For an illegal address in the SS segment  |
|                                    |      |               |                             | X      | If a memory address referencing the SS segment is in a non-canonical form             |
| General Protection, #GP(0)         |      |               | X                           |        | For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments. |
|                                    |      |               |                             | X      | If the memory address is in a non-canonical form.                                     |
|                                    | X    | X             |                             |        | If any part of the operand lies outside the effective address space from 0 to FFFFH   |
| Page Fault #PF(fault-code)         |      | X             | X                           | X      | For a page fault  |
| SIMD Floating-point Exception, #XM | X    | X             | X                           | X      | If an unmasked SIMD floating-point exception and CR4.OSXMMEXCPT[bit 10] = 1           |

## 7.5 FS/GS BASE SUPPORT FOR 64-BIT SOFTWARE

64-bit code can use new instructions to access and modify FS and GS base. These new instructions are available to software in all privilege levels. CR4 register bit 16 allows system software to control the availability of these instructions to software. CR4.FSGSBASE

FSGSBASE-Enable Bit (bit 16 of CR4) — Enables RDFSBASE/RDGSBASE/WRFSBASE/WRGSBASE instructions in all privilege levels when set. When clear, RDFSBASE/RDGSBASE/WRFSBASE/WRGSBASE instructions cause #UD in all privilege level. The default value of this bit is zero after RESET.

RDFSBASE/RDGSBASE/WRFSBASE/WRGSBASE instructions are available only 64-bit sub-mode of the IA-32e mode. Access to CR4.FSGSBASE is available in all operating modes if CPUID.(EAX=07H, ECX=0H):EBX.FSGSBASE is 1.

### NOTE

It is highly recommended that REX.W prefix is used with these instructions to read/write full 64-bit value. If REX.W prefix is omitted, when reading from segment base, upper 32-bits will be ignored and will be set to zero in destination registers. If REX.W prefix is omitted for write to segment base, the upper 32-bits of source register will be ignored and the corresponding bits for segment base will be set to zero. Additionally, if OS enables these instructions, they also context switch GS and FS base to ensure that any changes made by the applications to the segment base are appropriately context switched.

## 7.6 USING RDRAND INSTRUCTION AND INTRINSIC

Truly random numbers can help programmers improve the security of software agents running in a system. The RDRAND instruction provides a facility for programmers to achieve that goal. All Intel processors that support the RDRAND instruction indicate the availability of the RDRAND instruction via reporting CPUID.01H:ECX.RDRAND[bit 30] = 1.

The random numbers that are returned by the RDRAND instruction are supplied by a cryptographically secure Random Number Generator that employs a hardware DRBG (Digital Random Bit Generator, also known as a Pseudo Random Number Generator) seeded by a hardware NRBG (Nondeterministic Random Bit Generator, also known as a TRNG or True Random Number generator).

In order for the hardware design to meet its security goals, the random number generator continuously tests itself and the random data it is generating. Runtime failures in the random number generator circuitry or statistically anomalous data occurring by chance will be detected by the self test hardware and flag the resulting data as being bad. In such extremely rare cases, the RDRAND instruction will return no data instead of bad data.

Under heavy load, with multiple cores executing RDRAND in parallel, it is possible, though unlikely, for the demand of random numbers by software processes/threads to exceed the rate at which the random number generator hardware can supply them. This will lead to the RDRAND instruction returning no data transitorily. The RDRAND instruction indicates the occurrence of this rare situation by clearing the CF flag.

The RDRAND instruction returns with the carry flag set (CF = 1) to indicate data was returned. Software using the RDRAND instruction to get random numbers should retry for a limited number of iterations while RDRAND returns CF=0 and should complete when data is returned, indicated with CF=1. This will deal with transitory underflows. A retry limit should be employed to prevent a hard failure in the RNG (expected to be extremely rare) leading to a busy loop in software.

The intrinsic primitive for RDRAND is defined to address software's need for the common cases (CF = 1) and the rare situations (CF = 0). The intrinsic primitive returns a value that reflects the value of the carry flag returned by the underlying RDRAND instruction. The example below illustrates the recommended usage of an RDRAND intrinsic in a utility function, a loop to fetch a 64 bit random value with a retry count limit of 10. A C implementation might be written as follows:

```
-----  
#define SUCCESS 1  
#define RETRY_LIMIT_EXCEEDED 0  
#define RETRY_LIMIT 10  
  
int get_random_64( unsigned __int 64 * arand)  
{int i;  
  for ( i = 0; i < RETRY_LIMIT; i ++ ) {  
    if( _rdrand64_step( arand ) ) return SUCCESS;  
  }  
  return RETRY_LIMIT_EXCEEDED;  
}
```

## 7.7 INSTRUCTION REFERENCE

Conventions and notations of instruction format can be found in Section 5.1.

## RDFSBASE/RDGSBASE—Read FS/GS Segment Base Register

| Opcode/<br>Instruction                     | Op<br>En | 64/32 bit<br>Mode<br>Support | CPUID<br>Feature Flag | Description  |
|--|----------|------------------------------|-----------------------|--|
| F3 0F AE /0<br>RDFSBASE <i>r32</i>         | A        | V/I                          | FSGSBASE              | Read FS base register and place the 32-bit result in the destination register. |
| REX.W + F3 0F AE /0<br>RDFSBASE <i>r64</i> | A        | V/I                          | FSGSBASE              | Read FS base register and place the 64-bit result in the destination register. |
| F3 0F AE /1<br>RDGSBASE <i>r32</i>         | A        | V/I                          | FSGSBASE              | Read GS base register and place the 32-bit result in destination register.     |

## Instruction Operand Encoding

|   | Operand 1     | Operand2 | Operand3 | Operand4 |
|---|---------------|----------|----------|----------|
| A | ModRM:r/m (w) | NA       | NA       | NA       |

## Description

Loads the FS or GS segment base register into a general purpose register indicated by the modR/M:r/m field. The destination operand is a 32 or 64-bit general purpose register. The REX.W prefix indicates the operand size is 64 bit. If no REX.W prefix is used then the operand size is 32 bit and the upper 32 bits of the FS or GS base are ignored and bits [63:32] of the destination register will be written to 0.

This instruction is supported only in 64-bit sub mode of the IA-32e mode.

## Operation

If OperandSize = 64 then

DEST[63:0] ← FS/GS\_Segment\_Base\_Register;

Else

DEST[31:0] ← FS/GS\_Segment\_Base\_Register;

DEST[63:32] ← 0;

|   | Operand 1     | Operand2 | Operand3 | Operand4 |
|---|---------------|----------|----------|----------|
| A | ModRM:r/m (w) | NA       | NA       | NA       |

### Description

Loads a hardware generated random value and store it in the destination register. The size of the random value is determined by the destination register size and operating mode. The Carry Flag indicates whether a random value is available at the time the instruction is executed. CF=1 indicates that the data in the destination is valid. Otherwise CF=0 and the data in the destination operand will be returned as zeros for the specified width. All other flags are forced to 0 in either situation. Software must check the state of CF=1 for determining if a valid random value has been returned, otherwise it is expected to loop and retry execution of RDRAND (see Section 7.6).

This instruction is available at all privilege levels. For virtualization supporting lock-step operation, a virtualization control exists that allows the virtual machine monitor to trap on the instruction. "RDRAND exiting" will be controlled by bit 11 of the secondary processor-based VM-execution control. A VMEXIT due to RDRAND will have exit reason 57 (decimal).

In 64-bit mode, the instruction's default operation size is 32 bits. Using a REX prefix in the form of REX.B permits access to additional registers (R8-R15). Using a REX prefix in the form of REX.W promotes operation to 64 bit operands. See the summary chart at the beginning of this section for encoding data and limits.

### Operation

IF HW\_RND\_GEN.ready = 1

THEN

CASE of

osize is 64: DEST[63:0] ← HW\_RND\_GEN.data;

## WRFSBASE/WRGSBASE—Write FS/GS Segment Base Register

| Opcode/<br>Instruction              | Op<br>En | 64/32 bit<br>Mode<br>Support | CPUID<br>Feature Flag | Description  |
|-------------------------------------|----------|------------------------------|-----------------------|--|
| F3 0F AE /2<br>WRFSBASE r32         | A        | V/I                          | FSGSBASE              | Write the 32-bit value in the source register to FS base register. |
| REX.W + F3 0F AE /2<br>WRFSBASE r64 | A        | V/I                          | FSGSBASE              | Write the 64-bit value in the source register to FS base register. |
| F3 0F AE /3<br>WRGS-<br>BASE r32    | A        | V/I                          | FSGSBASE              | Write the 32-bit value in the source register to GS base register. |
| REX.W + F3 0F AE /3<br>WRGSBASE r64 | A        | V/I                          | FSGSBASE              | Write the 64-bit value in the source register to GS base register. |

### Instruction Operand Encoding

|   | Operand 1     | Operand2 | Operand3 | Operand4 |
|---|---------------|----------|----------|----------|
| A | ModRM:r/m (r) | NA       | NA       | NA       |

### Description

Loads the source operand into the FS or GS segment base register. The source operand is a 32 or 64-bit general purpose register. The REX.W prefix indicates the operand size is 64 bit. If no REX.W prefix is used then the operand size is 32 bit and the upper 32 bits of the FS or GS base register will be written to 0.

This instruction is supported only in 64-bit sub mode of the IA-32e mode.

### Operation

If osize = 64 then

FS/GS\_Segment\_Base\_Register ← SRC[63:0];

Else

FS/GS\_Segment\_Base\_Register[63:32] ← 0;

FS/GS\_Segment\_Base\_Register[31:0] ← SRC[31:0];

### Flags Affected

None

### C/C++ Compiler Intrinsic Equivalent

```

WRFSBASE void _writefsbase_u32( unsigned int );
WRFSBASE _writefsbase_u64( unsigned __int64 );
WRGSBASE void _writegsbase_u32( unsigned int );
WRGSBASE _writegsbase_u64( unsigned __int64 );

```

### Protected Mode Exceptions

| VEX.128.66.0F38.W0 13 /r<br>VCVTPH2PS xmm1, xmm2/m64  | A        | V/V                             | F16C                     | Convert four packed half precision (16-bit) floating-point values in xmm2/m64 to packed single-precision floating-point value in xmm1.   |

### Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:reg (w) | ModRM:r/m (r) | NA       | NA       |

#### Description

Converts four/eight packed half precision (16-bits) floating-point values in the low-order 64/128 bits of an XMM/YMM register or 64/128-bit memory location to four/eight packed single-precision floating-point values and writes the converted values into the destination XMM/YMM register.

If case of a denormal operand, the correct normal result is returned. MXCSR.DAZ is ignored and is treated as if it 0. No denormal exception is reported on MXCSR.

128-bit version: The source operand is a XMM register or 64-bit memory location. The destination operand is a XMM register. The upper bits (255:128) of the corresponding destination YMM register are zeroed.

256-bit version: The source operand is a XMM register or 128-bit memory location. The destination operand is a YMM register.

The diagram below illustrates how data is converted from four packed half precision (in 64 bits) to four single precision (in 128 bits) FP values.

Note: VEX.vvvv is reserved (must be 1111b).

Imm8 provides rounding controls. |
| VEX.128.66.0F3A.W0.1D /r ib<br>VCVTPS2PH xmm1/m64, xmm2, imm8  | A        | V/V                             | F16C                     | Convert four packed single-precision floating-point value in xmm2 to packed half-precision (16-bit) floating point value in xmm1/mem. Imm8 provides rounding controls.  |

## Instruction Operand Encoding

|   | Operand 1     | Operand2      | Operand3 | Operand4 |
|---|---------------|---------------|----------|----------|
| A | ModRM:r/m (w) | ModRM:reg (r) | NA       | NA       |

## Description

Convert four or eight packed single-precision floating values in first source operand to four or eight packed half-precision (16-bit) floating point values. The rounding mode are specified using the immediate field (imm8).

Underflow results (i.e. tiny results) are converted to denormals. MXCSR.FTZ is ignored. If a source element is denormal relative to input format with DM masked and at least one of PM or UM unmasked; a SIMD exception will be raised with DE, UE and PE set.

128-bit version: The source operand is a XMM register. The destination operand is a XMM register or 64-bit memory location. If destination operand is a register then the upper bits (255:64) of corresponding YMM register are zeroed.

256-bit version: The source operand is a YMM register. The destination operand is a XMM register or 128-bit memory location. If the destination operand is a register, the upper bits (255:128) of the corresponding YMM register are zeroed.

Note: VEX.vvvv is reserved (must be 1111b).

The diagram below illustrates how data is converted from four packed single precision (in 128 bits) to four half precision (in 64 bits) FP values.

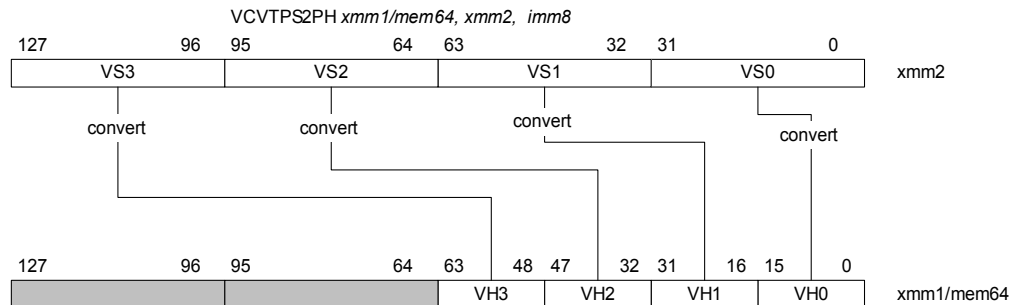

Figure 7-4. VCVTQPS2PH (128-bit Version)

The immediate byte defines several bit fields that controls rounding operation. The effect and encoding of RC field are listed in Table 7-12.

**Table 7-12. Immediate Byte Encoding for 16-bit Floating-Point Conversion Instructions**

| Bits     | Field Name/value | Description               | Comment         |
|----------|------------------|---------------------------|-----------------|
| Imm[1:0] | RC=00B           | Round to nearest even     | If Imm[2] = 0   |
|          | RC=01B           | Round down                |                 |

## APPENDIX A INSTRUCTION SUMMARY

---

Most SSE/SSE2/SSE3/SSSE3/SSE4 Instructions have been promoted to support VEX.128 encodings which, for non-memory-store versions implies support for zeroing upper bits of YMM registers. Table A-1 summarizes the promotion status for existing instructions. The column "VEX.256" indicates whether 256-bit vector form of the instruction using the VEX.256 prefix encoding is supported. The column "VEX.128" indicates whether the instruction using VEX.128 prefix encoding is supported.

Table A-1. Promoted SSE/SSE2/SSE3/SSSE3/SSE4 Instructions

| VEX.256 Encoding | VEX.128 Encoding | group    | Instruction | If No, Reason?            |
|------------------|------------------|----------|-------------|---------------------------|
| yes              | yes              | YY OF 1X | MOVUPS      |                           |
| no               | yes              |          | MOVSS       | scalar                    |
| yes              | yes              |          | MOVUPD      |                           |

| no                  | no                  | SSE4.2 | POPCNT      | integer        |

Description of Column "If No, Reason?"

**MMX:** Instructions referencing MMX registers do not support VEX

**Scalar:** Scalar instructions are not promoted to 256-bit

**integer:** integer instructions are not promoted.

**VI:** "Vector Integer" instructions are not promoted to 256-bit

**Note 1:** MOVLDP/PS and MOVHPD/PS are not promoted to 256-bit. The equivalent functionality are provided by VINSERTF128 and VEXTRACTF128 instructions as the existing instructions have no natural 256b extension

**Note 2:** BLENDVDP and BLENDVPS are superseded by the more flexible VBLENDVDP and VBLENDVPS.

**Note 3:** It is expected that using 128-bit INSERTPS followed by a VINSERTF128 would be better than promoting INSERTPS to 256-bit (for example).

Table A-2. AVX, FMA and AES New Instructions

| Opcode                    | Instruction                            | Description   |
|---------------------------|--|---|
| 66 0F 38 DE /r            | AESDEC xmm1, xmm2/m128                 | Perform 1 round of AES decryption of xmm1 using the 128-bit round key from the xmm2/m128.   |
| 66 0F 38 DF /r            | AESDECLAST xmm1, xmm2/m128             | Perform the last round of AES decryption of xmm1 using the 128 bit round key from xmm2/m128.  |
| VEX.NDS.128.66.0F38 DE /r | VAESDEC xmm1, xmm2, xmm3/m128          | Perform 1 round of AES decryption of xmm2 using the 128-bit round key from the xmm3/m128, and stores the result in xmm1.              |
| VEX.NDS.128.66.0F38 DF /r | VAESDECLAST xmm1, xmm2, xmm3/m128      | Perform the last round of AES decryption of xmm2 using the 128 bit round key from xmm3/m128, and stores the result in xmm1.           |

## APPENDIX B OPCODE MAP

---

Use the opcode tables in this chapter to interpret Intel® 64 and IA-32 architecture object code. Instructions are divided into encoding groups:

- 1-byte, 2-byte and 3-byte opcode encodings are used to encode integer, system, MMX technology, SSE/SSE2/SSE3/SSSE3/SSE4, and VMX instructions. Maps for these instructions are given in Table B-2 through Table B-6.
- Escape opcodes (in the format: ESC character, opcode, ModR/M byte) are used for floating-point instructions. The maps for these instructions are provided in Table B-7 through Table B-22.

### NOTE

All blanks in opcode maps are reserved and must not be used. Do not depend on the operation of undefined or blank opcodes.

## B.1 USING OPCODE TABLES

Tables in this appendix list opcodes of instructions (including required instruction prefixes, opcode extensions in associated ModR/M byte). Blank cells in the tables indicate opcodes that are reserved or undefined.

The opcode map tables are organized by hex values of the upper and lower 4 bits of an opcode byte. For 1-byte encodings (Table B-2), use the four high-order bits of an opcode to index a row of the opcode table; use the four low-order bits to index a column of the table. For 2-byte opcodes beginning with 0FH (Table B-3), skip any instruction prefixes, the 0FH byte (0FH may be preceded by 66H, F2H, or F3H) and use the upper and lower 4-bit values of the next opcode byte to index table rows and columns. Similarly, for 3-byte opcodes beginning with 0F38H or 0F3AH (Table B-4), skip any instruction prefixes, 0F38H or 0F3AH and use the upper and lower 4-bit values of the third opcode byte to index table rows and columns. See Section B.2.4, "Opcode Look-up Examples for One, Two, and Three-Byte Opcodes."

When a ModR/M byte provides opcode extensions, this information qualifies opcode execution. For information on how an opcode extension in the ModR/M byte modifies the opcode map in Table B-2 and Table B-3, see Section B.4.

The escape (ESC) opcode tables for floating point instructions identify the eight high order bits of opcodes at the top of each page. See Section B.5. If the accompanying ModR/M byte is in the range of 00H-BFH, bits 3-5 (the top row of the third table on each page) along with the reg bits of ModR/M determine the opcode. ModR/M bytes outside the range of 00H-BFH are mapped by the bottom two tables on each page of the section.

## B.2 KEY TO ABBREVIATIONS

Operands are identified by a two-character code of the form Zz. The first character, an uppercase letter, specifies the addressing method; the second character, a lowercase letter, specifies the type of operand.

### B.2.1 Codes for Addressing Method

The following abbreviations are used to document addressing methods:

- A Direct address: the instruction has no ModR/M byte; the address of the operand is encoded in the instruction. No base register, index register, or scaling factor can be applied (for example, far JMP (EA)).
- C The reg field of the ModR/M byte selects a control register (for example, MOV (0F20, 0F22)).
- D The reg field of the ModR/M byte selects a debug register (for example, MOV (0F21,0F23)).
- E A ModR/M byte follows the opcode and specifies the operand. The operand is either a general-purpose register or a memory address. If it is a memory address, the address is computed from a segment register and any of the following values: a base register, an index register, a scaling factor, a displacement.
- F EFLAGS/RFLAGS Register.
- G The reg field of the ModR/M byte selects a general register (for example, AX (000)).
- H The VEX.vvvv field of the VEX prefix selects a 128-bit XMM register or a 256-bit YMM register, determined by operand type. For legacy SSE encodings this operand does not exist, changing the instruction to destructive form.
- I Immediate data: the operand value is encoded in subsequent bytes of the instruction.
- J The instruction contains a relative offset to be added to the instruction pointer register (for example, JMP (0E9), LOOP).
- L The upper 4 bits of the 8-bit immediate selects a 128-bit XMM register or a 256-bit YMM register, determined by operand type. (the MSB is ignored in 32-bit mode)
- M The ModR/M byte may refer only to memory (for example, BOUND, LES, LDS, LSS, LFS, LGS, CMPXCHG8B).
- N The R/M field of the ModR/M byte selects a packed-quadword, MMX technology register.

- O The instruction has no ModR/M byte. The offset of the operand is coded as a word or double word (depending on address size attribute) in the instruction. No base register, index register, or scaling factor can be applied (for example, MOV (A0–A3)).
- P The reg field of the ModR/M byte selects a packed quadword MMX technology register.
- Q A ModR/M byte follows the opcode and specifies the operand. The operand is either an MMX technology register or a memory address. If it is a memory address, the address is computed from a segment register and any of the following values: a base register, an index register, a scaling factor, and a displacement.
- R The R/M field of the ModR/M byte may refer only to a general register (for example, MOV (0F20-0F23)).
- S The reg field of the ModR/M byte selects a segment register (for example, MOV (8C,8E)).
- U The R/M field of the ModR/M byte selects a 128-bit XMM register or a 256-bit YMM register, determined by operand type.
- V The reg field of the ModR/M byte selects a 128-bit XMM register or a 256-bit YMM register, determined by operand type.
- W A ModR/M byte follows the opcode and specifies the operand. The operand is either a 128-bit XMM register, a 256-bit YMM register (determined by operand type), or a memory address. If it is a memory address, the address is computed from a segment register and any of the following values: a base register, an index register, a scaling factor, and a displacement.
- X Memory addressed by the DS:rSI register pair (for example, MOVS, CMPS, OUTS, or LODS).
- Y Memory addressed by the ES:rDI register pair (for example, MOVS, CMPS, INS, STOS, or SCAS).

## B.2.2 Codes for Operand Type

The following abbreviations are used to document operand types:

- a Two one-word operands in memory or two double-word operands in memory, depending on operand-size attribute (used only by the BOUND instruction).
- b Byte, regardless of operand-size attribute.
- c Byte or word, depending on operand-size attribute.
- d Doubleword, regardless of operand-size attribute.
- dq Double-quadword, regardless of operand-size attribute.
- p 32-bit, 48-bit, or 80-bit pointer, depending on operand-size attribute.

## OPCODE MAP

|    |   |
|----|---|
| pd | 128-bit or 256-bit packed double-precision floating-point data.                     |
| pi | Quadword MMX technology register (for example: mm0).                                |
| ps | 128-bit or 256-bit packed single-precision floating-point data.                     |
| q  | Quadword, regardless of operand-size attribute.                                     |
| qq | Quad-Quadword (256-bits), regardless of operand-size attribute.                     |
| s  | 6-byte or 10-byte pseudo-descriptor.  |
| sd | Scalar element of a 128-bit double-precision floating data.                         |
| ss | Scalar element of a 128-bit single-precision floating data.                         |
| si | Doubleword integer register (for example: eax).                                     |
| v  | Word, doubleword or quadword (in 64-bit mode), depending on operand-size attribute. |
| w  | Word, regardless of operand-size attribute.   |
| x  | dq or qq based on the operand-size attribute.                                       |
| y  | Doubleword or quadword (in 64-bit mode), depending on operand-size attribute.       |
| z  | Word for 16-bit operand-size or doubleword for 32 or 64-bit operand-size.           |

### B.2.3 Register Codes

When an opcode requires a specific register as an operand, the register is identified by name (for example, AX, CL, or ESI). The name indicates whether the register is 64, 32, 16, or 8 bits wide.

A register identifier of the form eXX or rXX is used when register width depends on the operand-size attribute. eXX is used when 16 or 32-bit sizes are possible; rXX is used when 16, 32, or 64-bit sizes are possible. For example: eAX indicates that the AX register is used when the operand-size attribute is 16 and the EAX register is used when the operand-size attribute is 32. rAX can indicate AX, EAX or RAX.

When the REX.B bit is used to modify the register specified in the reg field of the opcode, this fact is indicated by adding "/x" to the register name to indicate the additional possibility. For example, rCX/r9 is used to indicate that the register could either be rCX or r9. Note that the size of r9 in this case is determined by the operand size attribute (just as for rCX).

### B.2.4 Opcode Look-up Examples for One, Two, and Three-Byte Opcodes

This section provides examples that demonstrate how opcode maps are used.

## B.2.4.1 One-Byte Opcode Instructions

The opcode map for 1-byte opcodes is shown in Table B-2. The opcode map for 1-byte opcodes is arranged by row (the least-significant 4 bits of the hexadecimal value) and column (the most-significant 4 bits of the hexadecimal value). Each entry in the table lists one of the following types of opcodes:

- Instruction mnemonics and operand types using the notations listed in Section B.2
- Opcodes used as an instruction prefix

For each entry in the opcode map that corresponds to an instruction, the rules for interpreting the byte following the primary opcode fall into one of the following cases:

- A ModR/M byte is required and is interpreted according to the abbreviations listed in Section B.1 and Chapter 2, “Instruction Format,” of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2A*. Operand types are listed according to notations listed in Section B.2.
- A ModR/M byte is required and includes an opcode extension in the reg field in the ModR/M byte. Use Table B-6 when interpreting the ModR/M byte.
- Use of the ModR/M byte is reserved or undefined. This applies to entries that represent an instruction prefix or entries for instructions without operands that use ModR/M (for example: 60H, PUSHA; 06H, PUSH ES).

### Example B-1. Look-up Example for 1-Byte Opcodes

Opcode 030500000000H for an ADD instruction is interpreted using the 1-byte opcode map (Table B-2) as follows:

- The first digit (0) of the opcode indicates the table row and the second digit (3) indicates the table column. This locates an opcode for ADD with two operands.
- The first operand (type Gv) indicates a general register that is a word or doubleword depending on the operand-size attribute. The second operand (type Ev) indicates a ModR/M byte follows that specifies whether the operand is a word or doubleword general-purpose register or a memory address.
- The ModR/M byte for this instruction is 05H, indicating that a 32-bit displacement follows (00000000H). The reg/opcode portion of the ModR/M byte (bits 3-5) is 000, indicating the EAX register.

The instruction for this opcode is ADD EAX, mem\_op, and the offset of mem\_op is 00000000H.

Some 1- and 2-byte opcodes point to group numbers (shaded entries in the opcode map table). Group numbers indicate that the instruction uses the reg/opcode bits in the ModR/M byte as an opcode extension (refer to Section B.4).

### B.2.4.2 Two-Byte Opcode Instructions

The two-byte opcode map shown in Table B-3 includes primary opcodes that are either two bytes or three bytes in length. Primary opcodes that are 2 bytes in length begin with an escape opcode 0FH. The upper and lower four bits of the second opcode byte are used to index a particular row and column in Table B-3.

Two-byte opcodes that are 3 bytes in length begin with a mandatory prefix (66H, F2H, or F3H) and the escape opcode (0FH). The upper and lower four bits of the third byte are used to index a particular row and column in Table B-3 (except when the second opcode byte is the 3-byte escape opcodes 38H or 3AH; in this situation refer to Section B.2.4.3).

For each entry in the opcode map, the rules for interpreting the byte following the primary opcode fall into one of the following cases:

- A ModR/M byte is required and is interpreted according to the abbreviations listed in Section B.1 and Chapter 2, “Instruction Format,” of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2A*. The operand types are listed according to notations listed in Section B.2.
- A ModR/M byte is required and includes an opcode extension in the reg field in the ModR/M byte. Use Table B-6 when interpreting the ModR/M byte.
- Use of the ModR/M byte is reserved or undefined. This applies to entries that represent an instruction without operands that are encoded using ModR/M (for example: 0F77H, EMMS).

#### Example B-2. Look-up Example for 2-Byte Opcodes

Look-up opcode 0FA405000000003H for a SHLD instruction using Table B-3.

- The opcode is located in row A, column 4. The location indicates a SHLD instruction with operands Ev, Gv, and Ib. Interpret the operands as follows:
  - Ev: The ModR/M byte follows the opcode to specify a word or doubleword operand.
  - Gv: The reg field of the ModR/M byte selects a general-purpose register.
  - Ib: Immediate data is encoded in the subsequent byte of the instruction.
- The third byte is the ModR/M byte (05H). The mod and opcode/reg fields of ModR/M indicate that a 32-bit displacement is used to locate the first operand in memory and eAX as the second operand.
- The next part of the opcode is the 32-bit displacement for the destination memory operand (0000000H). The last byte stores immediate byte that provides the count of the shift (03H).
- By this breakdown, it has been shown that this opcode represents the instruction: SHLD DS:0000000H, EAX, 3.

### B.2.4.3 Three-Byte Opcode Instructions

The three-byte opcode maps shown in Table B-4 and Table B-5 includes primary opcodes that are either 3 or 4 bytes in length. Primary opcodes that are 3 bytes in length begin with two escape bytes 0F38H or 0F3A. The upper and lower four bits of the third opcode byte are used to index a particular row and column in Table B-4 or Table B-5.

Three-byte opcodes that are 4 bytes in length begin with a mandatory prefix (66H, F2H, or F3H) and two escape bytes (0F38H or 0F3AH). The upper and lower four bits of the fourth byte are used to index a particular row and column in Table B-4 or Table B-5.

For each entry in the opcode map, the rules for interpreting the byte following the primary opcode fall into the following case:

- A ModR/M byte is required and is interpreted according to the abbreviations listed in B.1 and Chapter 2, "Instruction Format," of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*. The operand types are listed according to notations listed in Section B.2.

#### Example B-3. Look-up Example for 3-Byte Opcodes

Look-up opcode 660F3A0FC108H for a PALIGNR instruction using Table B-5.

- 66H is a prefix and 0F3AH indicate to use Table B-5. The opcode is located in row 0, column F indicating a PALIGNR instruction with operands Vdq, Wdq, and Ib. Interpret the operands as follows:
  - Vdq: The reg field of the ModR/M byte selects a 128-bit XMM register.
  - Wdq: The R/M field of the ModR/M byte selects either a 128-bit XMM register or memory location.
  - Ib: Immediate data is encoded in the subsequent byte of the instruction.
- The next byte is the ModR/M byte (C1H). The reg field indicates that the first operand is XMM0. The mod shows that the R/M field specifies a register and the R/M indicates that the second operand is XMM1.
- The last byte is the immediate byte (08H).
- By this breakdown, it has been shown that this opcode represents the instruction: PALIGNR XMM0, XMM1, 8.

### B.2.4.4 VEX Prefix Instructions

Instructions that include a VEX prefix are organized relative to the 2-byte and 3-byte opcode maps, based on the VEX.mmmmm field encoding of implied 0F, 0F38H, 0F3AH, respectively. Each entry in the opcode map of a VEX-encoded instruction is based on the value of the opcode byte, similar to non-VEX-encoded instructions.

A VEX prefix includes several bit fields that encode implied 66H, F2H, F3H prefix functionality (VEX.pp) and operand size/opcode information (VEX.L). See chapter 4 for details.

Opcode tables A2-A6 include both instructions with a VEX prefix and instructions without a VEX prefix. Many entries are only made once, but represent both the VEX and non-VEX forms of the instruction. If the VEX prefix is present all the operands are valid and the mnemonic is usually prefixed with a “v”. If the VEX prefix is not present the VEX.vvvv operand is not available.

A few instructions exist only in VEX form and these are marked with a superscript “v”.

Operand size of VEX prefix instructions can be determined by the operand type code. 128-bit vectors are indicated by 'dq', 256-bit vectors are indicated by 'qq', and instructions with operands supporting either 128 or 256-bit, determined by VEX.L, are indicated by 'x'. For example, the entry "VMOVUPD Vx,Wx" indicates both VEX.L=0 and VEX.L=1 are supported.

### B.2.5 Superscripts Utilized in Opcode Tables

Table B-1 contains notes on particular encodings. These notes are indicated in the following opcode maps by superscripts. Gray cells indicate instruction groupings.

**Table B-1. Superscripts Utilized in Opcode Tables**

| Superscript Symbol | Meaning of Symbol  |
|--------------------|--|
| 1A                 | Bits 5, 4, and 3 of ModR/M byte used as an opcode extension (refer to Section B.4, “Opcode Extensions For One-Byte And Two-byte Opcodes”).   |
| 1B                 | Use the 0F0B opcode (UD2 instruction) or the 0FB9H opcode when deliberately trying to generate an invalid opcode exception (#UD).  |
| 1C                 | Some instructions added in the Pentium III processor may use the same two-byte opcode. If the instruction has variations, or the opcode represents different instructions, the ModR/M byte will be used to differentiate the instruction. For the value of the ModR/M byte needed to decode the instruction, see Table B-6.<br><br>These instructions include SFENCE, STMXCSR, LDMXCSR, FXRSTOR, and FXSAVE, as well as PREFETCH and its variations. |
| i64                | The instruction is invalid or not encodable in 64-bit mode. 40 through 4F (single-byte INC and DEC) are REX prefix combinations when in 64-bit mode (use FE/FF Grp 4 and 5 for INC and DEC).   |
| o64                | Instruction is only available when in 64-bit mode.   |
| d64                | When in 64-bit mode, instruction defaults to 64-bit operand size and cannot encode 32-bit operand size.  |

**Table B-1. Superscripts Utilized in Opcode Tables**

| Superscript Symbol | Meaning of Symbol  |
|--------------------|--|
| f64                | The operand size is forced to a 64-bit operand size when in 64-bit mode (prefixes that change operand size are ignored for this instruction in 64-bit mode). |
| v                  | VEX form only exists. There is no legacy SSE form of the instruction.  |
| v1                 | VEX128 & SSE forms only exist (no VEX256), when can't be inferred from the data size.  |

### B.3 ONE, TWO, AND THREE-BYTE OPCODE MAPS

See Table B-2 through Table B-5 below. The tables are multiple page presentations. Rows and columns with sequential relationships are placed on facing pages to make look-up tasks easier. Note that table footnotes are not presented on each page. Table footnotes for each table are presented on the last page of the table.

Table B-2. One-byte Opcode Map: (00H – F7H) \*

|   | 0  | 1   | 2                             | 3  | 4  | 5  | 6                          | 7                     |
|---|--|---|-------------------------------|--|--|--|----------------------------|-----------------------|
| 0 | ADD  |   |                               |  |  |  | PUSH ES <sup>64</sup>      | POP ES <sup>64</sup>  |
|   | Eb, Gb   | Ev, Gv  | Gb, Eb                        | Gv, Ev   | AL, lb                                   | rAX, lz                                  |                            |                       |
| 1 | ADC  |   |                               |  |  |  | PUSH SS <sup>64</sup>      | POP SS <sup>64</sup>  |

| E |     |   |   |                                       |                                       |   |                                       |                            |                            |
| F |     |   |   |                                       |                                       |   |                                       |                            |                            |

**NOTES:**

\* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

## B.4 OPCODE EXTENSIONS FOR ONE-BYTE AND TWO-BYTE OPCODES

Some 1-byte and 2-byte opcodes use bits 3-5 of the ModR/M byte (the nnn field in Figure B-1) as an extension of the opcode.

|            |            |            |
|------------|------------|------------|
| <b>mod</b> | <b>nnn</b> | <b>R/M</b> |
|------------|------------|------------|

**Figure B-1. ModR/M Byte nnn Field (Bits 5, 4, and 3)**

Opcodes that have opcode extensions are indicated in Table B-6 and organized by group number. Group numbers (from 1 to 16, second column) provide a table entry point. The encoding for the r/m field for each instruction can be established using the third column of the table.

### B.4.1 Opcode Look-up Examples Using Opcode Extensions

An Example is provided below.

#### Example B-3. Interpreting an ADD Instruction

An ADD instruction with a 1-byte opcode of 80H is a Group 1 instruction:

- Table B-6 indicates that the opcode extension field encoded in the ModR/M byte for this instruction is 000B.
- The r/m field can be encoded to access a register (11B) or a memory address using a specified addressing mode (for example: mem = 00B, 01B, 10B).

#### Example B-2. Looking Up 0F01C3H

Look up opcode 0F01C3 for a VMRESUME instruction by using Table B-2, Table B-3 and Table B-6:

- 0F tells us that this instruction is in the 2-byte opcode map.
- 01 (row 0, column 1 in Table B-3) reveals that this opcode is in Group 7 of Table B-6.
- C3 is the ModR/M byte. The first two bits of C3 are 11B. This tells us to look at the second of the Group 7 rows in Table B-6.
- The Op/Reg bits [5,4,3] are 000B. This tells us to look in the 000 column for Group 7.
- Finally, the R/M bits [2,1,0] are 011B. This identifies the opcode as the VMRESUME instruction.

## B.4.2 Opcode Extension Tables

See Table B-6 below.

**Table B-6. Opcode Extensions for One- and Two-byte Opcodes by Group Number \***

| Opcode  | Group | Mod 7,6  | pfx  | Encoding of Bits 5,4,3 of the ModR/M Byte (bits 2,1,0 in parenthesis) |                                     |                            |   |                           |                |                           |                |

**NOTES:**

\* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

## B.5 ESCAPE OPCODE INSTRUCTIONS

Opcode maps for coprocessor escape instruction opcodes (x87 floating-point instruction opcodes) are in Table B-7 through Table B-22. These maps are grouped by the first byte of the opcode, from D8-DF. Each of these opcodes has a ModR/M byte. If the ModR/M byte is within the range of 00H-BFH, bits 3-5 of the ModR/M byte are used as an opcode extension, similar to the technique used for 1- and 2-byte opcodes (see B.4). If the ModR/M byte is outside the range of 00H through BFH, the entire ModR/M byte is used as an opcode extension.

### B.5.1 Opcode Look-up Examples for Escape Instruction Opcodes

Examples are provided below.

#### Example B-5. Opcode with ModR/M Byte in the 00H through BFH Range

DD0504000000H can be interpreted as follows:

- The instruction encoded with this opcode can be located in Section . Since the ModR/M byte (05H) is within the 00H through BFH range, bits 3 through 5 (000) of this byte indicate the opcode for an FLD double-real instruction (see Table B-9).
- The double-real value to be loaded is at 00000004H (the 32-bit displacement that follows and belongs to this opcode).

#### Example B-3. Opcode with ModR/M Byte outside the 00H through BFH Range

D8C1H can be interpreted as follows:

- This example illustrates an opcode with a ModR/M byte outside the range of 00H through BFH. The instruction can be located in Section B.4.
- In Table B-8, the ModR/M byte C1H indicates row C, column 1 (the FADD instruction using ST(0), ST(1) as operands).

### B.5.2 Escape Opcode Instruction Tables

Tables are listed below.

### B.5.2.1 Escape Opcodes with D8 as First Byte

Table B-7 and B-8 contain maps for the escape instruction opcodes that begin with D8H. Table B-7 shows the map if the ModR/M byte is in the range of 00H-BFH. Here, the value of bits 3-5 (the nnn field in Figure B-1) selects the instruction.

**Table B-7. D8 Opcode Map When ModR/M Byte is Within 00H to BFH \***

| nnn Field of ModR/M Byte (refer to Figure B.4) |                  |                  |                   |                  |                   |                  |                   |
|--|------------------|------------------|-------------------|------------------|-------------------|------------------|-------------------|
| 000B   | 001B             | 010B             | 011B              | 100B             | 101B              | 110B             | 111B              |
| FADD single-real                               | FMUL single-real | FCOM single-real | FCOMP single-real | FSUB single-real | FSUBR single-real | FDIV single-real | FDIVR single-real |

**NOTES:**

- \* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

Table B-8 shows the map if the ModR/M byte is outside the range of 00H-BFH. Here, the first digit of the ModR/M byte selects the table row and the second digit selects the column.

**Table B-8. D8 Opcode Map When ModR/M Byte is Outside 00H to BFH \***

|   | 0           | 1           | 2           | 3           | 4           | 5           | 6           | 7           |
|---|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| C | FADD        |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |
| D | FCOM        |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),T(2)  | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |

|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |
| F | FDIV        |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |

|   | 8           | 9           | A           | B           | C           | D           | E           | F           |
|---|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| C | FMUL        |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |
| D | FCOMP       |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),T(2)  | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |
| E | FSUBR       |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |
| F | FDIVR       |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |

**NOTES:**

- \* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

### B.5.2.2 Escape Opcodes with D9 as First Byte

Table B-9 and B-10 contain maps for escape instruction opcodes that begin with D9H. Table B-9 shows the map if the ModR/M byte is in the range of 00H-BFH. Here, the value of bits 3-5 (the nnn field in Figure B-1) selects the instruction.

**Table B-9. D9 Opcode Map When ModR/M Byte is Within 00H to BFH \***

| nnn Field of ModR/M Byte |      |                    |                     |                       |                  |                       |                  |
|--------------------------|------|--------------------|---------------------|-----------------------|------------------|-----------------------|------------------|
| 000B                     | 001B | 010B               | 011B                | 100B                  | 101B             | 110B                  | 111B             |
| FLD<br>single-real       |      | FST<br>single-real | FSTP<br>single-real | FLDENV<br>14/28 bytes | FLDCW<br>2 bytes | FSTENV<br>14/28 bytes | FSTCW<br>2 bytes |

**NOTES:**

\* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

Table B-10 shows the map if the ModR/M byte is outside the range of 00H-BFH. Here, the first digit of the ModR/M byte selects the table row and the second digit selects the column.

**Table B-10. D9 Opcode Map When ModR/M Byte is Outside 00H to BFH \***

|   | 0           | 1           | 2           | 3           | 4           | 5           | 6           | 7           |
|---|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| C | FLD         |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |
| D | FNOP        |             |             |             |             |             |             |             |
| E | FCHS        | FABS        |             |             | FTST        | FXAM        |             |             |
| F | F2XM1       | FYL2X       | FPTAN       | FPATAN      | FXTRACT     | FPREM1      | FDECSTP     | FINCSTP     |

|   | 8           | 9           | A           | B           | C           | D           | E           | F           |
|---|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| C | FXCH        |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |
| D |             |             |             |             |             |             |             |             |
| E | FLD1        | FLDL2T      | FLDL2E      | FLDPI       | FLDLG2      | FLDLN2      | FLDZ        |             |
| F | FPREM       | FYL2XP1     | FSQRT       | FSINCOS     | FRNDINT     | FSCALE      | FSIN        | FCOS        |

**NOTES:**

\* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

### B.5.2.3 Escape Opcodes with DA as First Byte

Table B-11 and B-12 contain maps for escape instruction opcodes that begin with DAH. Table B-11 shows the map if the ModR/M byte is in the range of 00H-BFH. Here, the value of bits 3-5 (the nnn field in Figure B-1) selects the instruction.

**Table B-11. DA Opcode Map When ModR/M Byte is Within 00H to BFH \***

| nnn Field of ModR/M Byte |                        |                        |                         |                        |                         |                        |                         |
|--------------------------|------------------------|------------------------|-------------------------|------------------------|-------------------------|------------------------|-------------------------|
| 000B                     | 001B                   | 010B                   | 011B                    | 100B                   | 101B                    | 110B                   | 111B                    |
| FIADD<br>dword-integer   | FIMUL<br>dword-integer | FICOM<br>dword-integer | FICOMP<br>dword-integer | FISUB<br>dword-integer | FISUBR<br>dword-integer | FIDIV<br>dword-integer | FIDIVR<br>dword-integer |

**NOTES:**

\* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

Table B-11 shows the map if the ModR/M byte is outside the range of 00H-BFH. Here, the first digit of the ModR/M byte selects the table row and the second digit selects the column.

**Table B-12. DA Opcode Map When ModR/M Byte is Outside 00H to BFH \***

|   | 0           | 1           | 2           | 3           | 4           | 5           | 6           | 7           |

|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |
| D | FCMOVU      |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |
| E |             | FUCOMPP     |             |             |             |             |             |             |
| F |             |             |             |             |             |             |             |             |

**NOTES:**

\* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

### B.5.2.4 Escape Opcodes with DB as First Byte

Table B-13 and B-14 contain maps for escape instruction opcodes that begin with DBH. Table B-13 shows the map if the ModR/M byte is in the range of 00H-BFH. Here, the value of bits 3-5 (the nnn field in Figure B-1) selects the instruction.

**Table B-13. DB Opcode Map When ModR/M Byte is Within 00H to BFH \***

| nnn Field of ModR/M Byte |                         |                       |                        |      |                      |      |                       |
|--------------------------|-------------------------|-----------------------|------------------------|------|----------------------|------|-----------------------|
| 000B                     | 001B                    | 010B                  | 011B                   | 100B | 101B                 | 110B | 111B                  |
| FILD<br>dword-integer    | FISTTP<br>dword-integer | FIST<br>dword-integer | FISTP<br>dword-integer |      | FLD<br>extended-real |      | FSTP<br>extended-real |

**NOTES:**

\* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

Table B-14 shows the map if the ModR/M byte is outside the range of 00H-BFH. Here, the first digit of the ModR/M byte selects the table row and the second digit selects the column.

**Table B-14. DB Opcode Map When ModR/M Byte is Outside 00H to BFH \***

|   | 0           | 1           | 2           | 3           | 4           | 5           | 6           | 7           |
|---|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| C | FCMOVNB     |             |             |             |             |             |             |             |

| D | FCMOVNBE    |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |
| E |             |             | FCLEX       | FINIT       |             |             |             |             |
| F | FCOMI       |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |

|   | 8           | 9           | A           | B           | C           | D           | E           | F           |
|---|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| C | FCMOVNE     |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |
| D | FCMOVNU     |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |
| E | FUCOMI      |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(0),ST(1) | ST(0),ST(2) | ST(0),ST(3) | ST(0),ST(4) | ST(0),ST(5) | ST(0),ST(6) | ST(0),ST(7) |
| F |             |             |             |             |             |             |             |             |

**NOTES:**

\* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

### B.5.2.5 Escape Opcodes with DC as First Byte

Table B-15 and B-16 contain maps for escape instruction opcodes that begin with DCH. Table B-15 shows the map if the ModR/M byte is in the range of 00H-BFH. Here, the value of bits 3-5 (the nnn field in Figure B-1) selects the instruction.

**Table B-15. DC Opcode Map When ModR/M Byte is Within 00H to BFH \***

| nnn Field of ModR/M Byte (refer to Figure B-1) |                  |                  |                   |                  |                   |                  |                   |
|--|------------------|------------------|-------------------|------------------|-------------------|------------------|-------------------|
| 000B   | 001B             | 010B             | 011B              | 100B             | 101B              | 110B             | 111B              |
| FADD double-real                               | FMUL double-real | FCOM double-real | FCOMP double-real | FSUB double-real | FSUBR double-real | FDIV double-real | FDIVR double-real |

**NOTES:**

\* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

Table B-16 shows the map if the ModR/M byte is outside the range of 00H-BFH. In this case the first digit of the ModR/M byte selects the table row and the second digit selects the column.

**Table B-16. DC Opcode Map When ModR/M Byte is Outside 00H to BFH \***

|   | 0           | 1           | 2           | 3           | 4           | 5           | 6           | 7           |
|---|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| C | FADD        |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(1),ST(0) | ST(2),ST(0) | ST(3),ST(0) | ST(4),ST(0) | ST(5),ST(0) | ST(6),ST(0) | ST(7),ST(0) |
| D |             |             |             |             |             |             |             |             |
|   |             |             |             |             |             |             |             |             |
| E | FSUBR       |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(1),ST(0) | ST(2),ST(0) | ST(3),ST(0) | ST(4),ST(0) | ST(5),ST(0) | ST(6),ST(0) | ST(7),ST(0) |
| F | FDIVR       |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(1),ST(0) | ST(2),ST(0) | ST(3),ST(0) | ST(4),ST(0) | ST(5),ST(0) | ST(6),ST(0) | ST(7),ST(0) |

|   | 8           | 9           | A           | B           | C           | D           | E           | F           |
|---|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| C | FMUL        |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(1),ST(0) | ST(2),ST(0) | ST(3),ST(0) | ST(4),ST(0) | ST(5),ST(0) | ST(6),ST(0) | ST(7),ST(0) |
| D |             |             |             |             |             |             |             |             |
|   |             |             |             |             |             |             |             |             |
| E | FSUB        |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(1),ST(0) | ST(2),ST(0) | ST(3),ST(0) | ST(4),ST(0) | ST(5),ST(0) | ST(6),ST(0) | ST(7),ST(0) |
| F | FDIV        |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(1),ST(0) | ST(2),ST(0) | ST(3),ST(0) | ST(4),ST(0) | ST(5),ST(0) | ST(6),ST(0) | ST(7),ST(0) |

**NOTES:**

\* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

### B.5.2.6 Escape Opcodes with DD as First Byte

Table B-17 and B-18 contain maps for escape instruction opcodes that begin with DDH. Table B-17 shows the map if the ModR/M byte is in the range of 00H-BFH. Here, the value of bits 3-5 (the nnn field in Figure B-1) selects the instruction.

**Table B-17. DD Opcode Map When ModR/M Byte is Within 00H to BFH \***

| nnn Field of ModR/M Byte |                  |                 |                  |                    |      |                   |               |
|--------------------------|------------------|-----------------|------------------|--------------------|------|-------------------|---------------|
| 000B                     | 001B             | 010B            | 011B             | 100B               | 101B | 110B              | 111B          |
| FLD double-real          | FISTTP integer64 | FST double-real | FSTP double-real | FRSTOR 98/108bytes |      | FSAVE 98/108bytes | FSTSW 2 bytes |

**NOTES:**

\* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

Table B-18 shows the map if the ModR/M byte is outside the range of 00H-BFH. The first digit of the ModR/M byte selects the table row and the second digit selects the column.

**Table B-18. DD Opcode Map When ModR/M Byte is Outside 00H to BFH \***

|   | 0           | 1           | 2           | 3           | 4           | 5           | 6           | 7           |
|---|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| C | FFREE       |             |             |             |             |             |             |             |
|   | ST(0)       | ST(1)       | ST(2)       | ST(3)       | ST(4)       | ST(5)       | ST(6)       | ST(7)       |
| D | FST         |             |             |             |             |             |             |             |
|   | ST(0)       | ST(1)       | ST(2)       | ST(3)       | ST(4)       | ST(5)       | ST(6)       | ST(7)       |
| E | FUCOM       |             |             |             |             |             |             |             |
|   | ST(0),ST(0) | ST(1),ST(0) | ST(2),ST(0) | ST(3),ST(0) | ST(4),ST(0) | ST(5),ST(0) | ST(6),ST(0) | ST(7),ST(0) |
| F |             |             |             |             |             |             |             |             |

|   | 8      | 9     | A     | B     | C     | D     | E     | F     |
|---|--------|-------|-------|-------|-------|-------|-------|-------|
| C |        |       |       |       |       |       |       |       |
|   |        |       |       |       |       |       |       |       |
| D | FSTP   |       |       |       |       |       |       |       |
|   | ST(0)  | ST(1) | ST(2) | ST(3) | ST(4) | ST(5) | ST(6) | ST(7) |
| E | FUCOMP |       |       |       |       |       |       |       |
|   | ST(0)  | ST(1) | ST(2) | ST(3) | ST(4) | ST(5) | ST(6) | ST(7) |
| F |        |       |       |       |       |       |       |       |

**NOTES:**

\* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

### B.5.2.7 Escape Opcodes with DE as First Byte

Table B-19 and B-20 contain opcode maps for escape instruction opcodes that begin with DEH. Table B-19 shows the opcode map if the ModR/M byte is in the range of 00H-BFH. In this case, the value of bits 3-5 (the nnn field in Figure B-1) selects the instruction.

**Table B-19. DE Opcode Map When ModR/M Byte is Within 00H to BFH \***

| nnn Field of ModR/M Byte |                       |                       |                        |                       |                        |                       |                        |
|--------------------------|-----------------------|-----------------------|------------------------|-----------------------|------------------------|-----------------------|------------------------|
| 000B                     | 001B                  | 010B                  | 011B                   | 100B                  | 101B                   | 110B                  | 111B                   |
| FIADD<br>word-integer    | FIMUL<br>word-integer | FICOM<br>word-integer | FICOMP<br>word-integer | FISUB<br>word-integer | FISUBR<br>word-integer | FIDIV<br>word-integer | FIDIVR<br>word-integer |

**NOTES:**

\* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

Table B-20 shows the opcode map if the ModR/M byte is outside the range of 00H-BFH. The first digit of the ModR/M byte selects the table row and the second digit selects the column.

**Table B-20. DE Opcode Map When ModR/M Byte is Outside 00H to BFH \***

|   | 0           | 1           | 2           | 3           | 4           | 5           | 6           | 7           |

**NOTES:**

\* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

### B.5.2.8 Escape Opcodes with DF As First Byte

Table B-21 and B-22 contain the opcode maps for escape instruction opcodes that begin with DFH. Table B-21 shows the opcode map if the ModR/M byte is in the range of 00H-BFH. Here, the value of bits 3-5 (the nnn field in Figure B-1) selects the instruction.

**Table B-21. DF Opcode Map When ModR/M Byte is Within 00H to BFH \***

| nnn Field of ModR/M Byte |                     |                   |                    |                 |                    |                  |                     |
|--------------------------|---------------------|-------------------|--------------------|-----------------|--------------------|------------------|---------------------|
| 000B                     | 001B                | 010B              | 011B               | 100B            | 101B               | 110B             | 111B                |
| FILD word-integer        | FISTTP word-integer | FIST word-integer | FISTP word-integer | FBLD packed-BCD | FILD qword-integer | FBSTP packed-BCD | FISTP qword-integer |

**NOTES:**

- \* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

Table B-22 shows the opcode map if the ModR/M byte is outside the range of 00H-BFH. The first digit of the ModR/M byte selects the table row and the second digit selects the column.

**Table B-22. DF Opcode Map When ModR/M Byte is Outside 00H to BFH \***

|   | 0           | 1           | 2           | 3           | 4           | 5           | 6           | 7           |

**NOTES:**

- \* All blanks in all opcode maps are reserved and must not be used. Do not depend on the operation of undefined or reserved locations.

## OPCODE MAP

# INDEX

## A

|  |      |
|--|------|
| ADDPD - Add Packed Double Precision Floating-Point Values                        | 5-15 |
| ADDPS- Add Packed Single Precision Floating-Point Values                         | 5-17 |
| ADDSD- Add Scalar Double Precision Floating-Point Values                         | 5-19 |
| ADDSS- Add Scalar Single Precision Floating-Point Values                         | 5-21 |
| ADDSUBPD- Packed Double FP Add/Subtract  | 5-23 |
| ADDSUBPS- Packed Single FP Add/Subtract  | 5-25 |
| AESDEC/AESDECLAST- Perform One Round of an AES Decryption Flow                   | 5-30 |
| AESENC/AESENCLAST- Perform One Round of an AES Encryption Flow                   | 5-27 |
| AESIMC- Perform the AES InvMixColumn Transformation                              | 5-33 |
| AESKEYGENASSIST - AES Round Key Generation Assist                                | 5-35 |
| ANDNPD- Bitwise Logical AND NOT of Packed Double Precision Floating-Point Values | 5-41 |
| ANDNPS- Bitwise Logical AND NOT of Packed Single Precision Floating-Point Values | 5-43 |
| ANDPD- Bitwise Logical AND of Packed Double Precision Floating-Point Values      | 5-37 |
| ANDPS- Bitwise Logical AND of Packed Single Precision Floating-Point Values      | 5-39 |

## B

|   |      |
|---|------|
| BLENDPD- Blend Packed Double Precision Floating-Point Values  | 5-45 |
| BLENDPS- Blend Packed Single Precision Floating-Point Values  | 5-47 |
| BLENDVPD- Blend Packed Double Precision Floating-Point Values | 5-50 |
| BLENDVPS- Blend Packed Single Precision Floating-Point Values | 5-53 |
| Brand information   | 2-57 |
| processor brand index   | 2-61 |
| processor brand string  | 2-58 |

## C

|  |                              |
|--|------------------------------|
| Cache and TLB information  | 2-52                         |
| Cache Inclusiveness  | 2-34                         |
| CLFLUSH instruction  |                              |
| CPUID flag   | 2-51                         |
| CMOVcc flag  | 2-51                         |

| DIVPD- Divide Packed Double-Precision Floating-Point Values        | 5-127 |
| DIVPS- Divide Packed Single-Precision Floating-Point Values        | 5-129 |
| DIVSD- Divide Scalar Double-Precision Floating-Point Values        | 5-131 |
| DIVSS- Divide Scalar Single-Precision Floating-Point Values        | 5-133 |
| DPPD- Dot Product of Packed Double-Precision Floating-Point Values | 5-135 |
| DPPS- Dot Product of Packed Single-Precision Floating-Point Values | 5-137 |

## E

|   |       |
|---|-------|
| EXTRACTPS- Extract packed floating-point values | 5-142 |
|---|-------|

## F

|                                |          |
|--------------------------------|----------|
| Feature information, processor | 2-31     |
| Floating-point data types      |          |
| denormalized finite number     | 7-3      |
| infinities                     | 7-3      |
| normalized finite number       | 7-3      |
| storing in memory              | 7-5      |
| zeros                          | 7-3      |
| Floating-point format          |          |
| indefinite                     | 7-4      |
| Floating-point numbers         |          |
| encoding                       | 7-4      |
| FMA operation                  | 2-6, 2-7 |
| FXRSTOR instruction            |          |
| CPUID flag                     | 2-51     |
| FXSAVE instruction             | 5-530    |
| CPUID flag                     | 2-51     |

## H

|  |       |
|--|-------|
| HADDPD- Add Horizontal Double Precision Floating-Point Values      | 5-144 |
| HADDPs- Add Horizontal Single Precision Floating-Point Values      | 5-147 |
| HSUBPD- Subtract Horizontal Double Precision Floating-Point Values | 5-150 |
| HSUBPS- Subtract Horizontal Single Precision Floating-Point Values | 5-153 |
| Hyper-Threading Technology   |       |
| CPUID flag   | 2-52  |

## I

|   |       |
|---|-------|
| IA-32e mode   |       |
| CPUID flag .....  | 2-40  |
| Indefinite  |       |
| floating-point format .....   | 7-4   |
| Infinity, floating-point format .....                               | 7-3   |
| INSERTPS- Insert Scalar Single Precision Floating-Point Value ..... | 5-158 |

## L

|                                     |                         |
|-------------------------------------|-------------------------|
| L1 Context ID .....                 | 2-47                    |
| LDDQU- Move Unaligned Integer ..... | 5-162                   |
| LDMXCSR instruction .....           | 5-164, 7-13, 7-15, 7-18 |

## M

|  |       |
|--|-------|
| Machine check architecture   |       |
| CPUID flag .....   | 2-51  |
| description .....  | 2-51  |
| MASKMOVDQU- Store Selected Bytes of Double Quadword with NT Hint .....                     | 5-166 |
| MAXPD- Maximum of Packed Double Precision Floating-Point Values .....                      | 5-173 |
| MAXPS- Minimum of Packed Single Precision Floating-Point Values .....                      | 5-176 |
| MAXSD- Return Maximum Scalar Double-Precision Floating-Point Value .....                   | 5-179 |
| MAXSS- Return Maximum Scalar Single-Precision Floating-Point Value .....                   | 5-181 |
| MINPD- Minimum of Packed Double Precision Floating-Point Values .....                      | 5-183 |
| MINPS- Minimum of Packed Single Precision Floating-Point Values .....                      | 5-186 |
| MINSD- Return Minimum Scalar Double-Precision Floating-Point Value .....                   | 5-189 |
| MINSS- Return Minimum Scalar Single-Precision Floating-Point Value .....                   | 5-191 |
| MMX instructions   |       |
| CPUID flag for technology .....  | 2-51  |
| Model & family information .....   | 2-56  |
| MONITOR instruction  |       |
| CPUID flag .....   | 2-46  |
| feature data .....   | 2-56  |
| MOVAPD- Move Aligned Packed Double-Precision Floating-Point Values .....                   | 5-193 |
| MOVAPS- Move Aligned Packed Single-Precision Floating-Point Values .....                   | 5-196 |
| MOVDDUP- Replicate Double FP Values .....  | 5-205 |
| MOVDQA- Move Aligned Packed Integer Values .....   | 5-207 |
| MOVDQU- Move Unaligned Packed Integer Values .....   | 5-210 |
| MOVQ/MOVQ- Move Doubleword and Quadword .....  | 5-199 |
| MOVHLPS - Move Packed Single-Precision Floating-Point Values High to Low .....             | 5-213 |
| MOVHPD- Move High Packed Double-Precision Floating-Point Values .....                      | 5-215 |
| MOVHPS- Move High Packed Single-Precision Floating-Point Values .....                      | 5-217 |
| MOVLHPS - Move Packed Single-Precision Floating-Point Values Low to High .....             | 5-213 |
| MOVLPD- Move Low Packed Double-Precision Floating-Point Values .....                       | 5-221 |
| MOVLPS- Move Low Packed Single-Precision Floating-Point Values .....                       | 5-223 |
| MOVMSKPD- Extract Double-Precision Floating-Point Sign mask .....                          | 5-225 |
| MOVMSKPS- Extract Single-Precision Floating-Point Sign mask .....                          | 5-227 |
| MOVNTDQ- Store Packed Integers Using Non-Temporal Hint .....                               | 5-229 |
| MOVNTDQA- Load Double Quadword Non-Temporal Aligned Hint .....                             | 5-231 |
| MOVNTPD- Store Packed Double-Precision Floating-Point Values Using Non-Temporal Hint ..... | 5-233 |
| MOVNTPS- Store Packed Single-Precision Floating-Point Values Using Non-Temporal Hint ..... | 5-235 |
| MOVQ- Move Quadword .....  | 5-202 |
| MOVSD- Move or Merge Scalar Double-Precision Floating-Point Value .....                    | 5-237 |
| MOVSHDUP- Replicate Single FP Values .....   | 5-240 |
| MOVSLDUP- Replicate Single FP Values .....   | 5-243 |
| MOVSS- Move or Merge Scalar Single-Precision Floating-Point Value .....                    | 5-246 |
| MOVUPD- Move Unaligned Packed Double-Precision Floating-Point Values .....                 | 5-249 |
| MOVUPS- Move Unaligned Packed Single-Precision Floating-Point Values .....                 | 5-252 |
| MPSADBW - Multiple Sum of Absolute Differences .....                                       | 5-255 |
| MULPD- Multiply Packed Double Precision Floating-Point Values .....                        | 5-260 |
| MULPS- Multiply Packed Single Precision Floating-Point Values .....                        | 5-262 |

|   |       |
|---|-------|
| MULSD- Multiply Scalar Double-Precision Floating-Point Values | 5-264 |
| MULSS- Multiply Scalar Single-Precision Floating-Point Values | 5-266 |
| MWAIT instruction   |       |
| CPUID flag  | 2-46  |
| feature data  | 2-56  |

## N

|                          |          |
|--------------------------|----------|
| NaNs                     |          |
| encoding of              | 7-3, 7-4 |
| Normalized finite number | 7-3      |

## O

|   |                 |
|---|-----------------|
| Opcodes   |                 |
| addressing method codes for   | B-2             |
| extensions  | B-20            |
| extensions tables   | B-21            |
| group numbers   | B-20            |
| integers  |                 |
| one-byte opcodes  | B-10            |
| two-byte opcodes  | B-12            |
| key to abbreviations  | B-2             |
| look-up examples  | B-5, B-20, B-23 |
| ModR/M byte   | B-20            |
| one-byte opcodes  | B-5, B-10       |
| opcode maps   | B-1             |
| operand type codes for  | B-3             |
| register codes for  | B-4             |
| superscripts in tables  | B-8             |
| two-byte opcodes  | B-6, B-7, B-12  |
| x87 ESC instruction opcodes   | B-23            |
| ORPD- Bitwise Logical OR of Packed Double Precision Floating-Point Values | 5-268           |
| ORPS- Bitwise Logical OR of Packed Single Precision Floating-Point Values | 5-270           |

## P

|   |       |
|---|-------|
| PABSB/PABSW/PABSD - Packed Absolute Value                                 | 5-272 |
| PACKSSWB/PACKSSDW - Pack with Signed Saturation                           | 5-275 |
| PACKUSWB/PACKUSDW - Pack with Unsigned Saturation                         | 5-279 |
| PADDB/PADDW/PADDD/PADDQ- Add Packed Integers                              | 5-282 |
| PADDSB/PADDSW- Add Packed Signed Integers with Signed Saturation          | 5-286 |
| PADDUSB/PADDUSW- Add Packed Unsigned Integers with Unsigned Saturation    | 5-289 |
| PALIGNR - Byte Align  | 5-292 |
| PAND- Logical AND   | 5-294 |
| PANDN- Logical AND NOT  | 5-296 |
| PAVGB/PAVGW - Average Packed Integers                                     | 5-298 |
| PBLENDVB - Variable Blend Packed Bytes                                    | 5-300 |
| PBLENDW - Blend Packed Words  | 5-304 |
| PCLMULQDQ - Carry-Less Multiplication Quadword                            | 5-307 |
| PCMPEQB/PCMPEQW/PCMPEQD/PCMPEQQ- Compare Packed Integers for Equality     | 5-319 |
| PCMPSTR - Packed Compare Explicit Length Strings, Return Index            | 5-315 |
| PCMPSTRM - Packed Compare Explicit Length Strings, Return Mask            | 5-317 |
| PCMPGTB/PCMPGTW/PCMPGTD/PCMPGTQ- Compare Packed Integers for Greater Than | 5-319 |
| PCMPISTRI - Packed Compare Implicit Length Strings, Return Index          | 5-323 |
| PCMPISTRM - Packed Compare Implicit Length Strings, Return Mask           | 5-325 |
| Pending break enable  | 2-52  |
| Performance-monitoring counters   |       |
| CPUID inquiry for   | 2-57  |
| PEXTRB/PEXTRW/PEXTRD/PEXTRQ- Extract Integer                              | 5-337 |
| PHADDSW - Packed Horizontal Add with Saturation                           | 5-344 |
| PHADDW/PHADDD - Packed Horizontal Add                                     | 5-341 |

|   |       |
|---|-------|
| PHMINPOSUW - Horizontal Minimum and Position                                | 5-346 |
| PHSUBSW - Packed Horizontal Subtract with Saturation                        | 5-351 |
| PHSUBW/PHSUBD - Packed Horizontal Subtract                                  | 5-348 |
| PINSRB/PINSRW/PINSRD/PINSRQ- Insert Integer                                 | 5-353 |
| PMADDUBSW- Multiply and Add Packed Integers                                 | 5-360 |
| PMADDWD- Multiply and Add Packed Integers                                   | 5-358 |
| PMASB/PMASW/PMASD- Maximum of Packed Signed Integers                        | 5-362 |
| PMAXUB/PMAXUW/PMAXUD- Maximum of Packed Unsigned Integers                   | 5-366 |
| PMINSB/PMINSW/PMINSUD- Minimum of Packed Signed Integers                    | 5-370 |
| PMINUB/PMINUW/PMINUD- Minimum of Packed Unsigned Integers                   | 5-374 |
| PMOVMASK- Move Byte Mask  | 5-378 |
| PMOVSX - Packed Move with Sign Extend                                       | 5-347 |
| PMOVZX - Packed Move with Zero Extend                                       | 5-385 |
| PMULDQ - Multiply Packed Doubleword Integers                                | 5-401 |
| PMULHSW - Multiply Packed Unsigned Integers with Round and Shift            | 5-392 |
| PMULHUW - Multiply Packed Unsigned Integers and Store High Result           | 5-390 |
| PMULHW - Multiply Packed Integers and Store High Result                     | 5-394 |
| PMULLW/PMULLD - Multiply Packed Integers and Store Low Result               | 5-396 |
| PMULUDQ - Multiply Packed Unsigned Doubleword Integers                      | 5-399 |
| POR - Bitwise Logical Or  | 5-403 |
| PSADBW - Compute Sum of Absolute Differences                                | 5-405 |
| PSHUFB - Packed Shuffle Bytes   | 5-407 |
| PSHUFD - Shuffle Packed Doublewords   | 5-409 |
| PSHUFHW - Shuffle Packed High Words   | 5-412 |
| PSHUFLW - Shuffle Packed Low Words  | 5-414 |
| PSIGNB/PSIGNW/PSIGND - Packed SIGN  | 5-416 |
| PSLLDQ - Byte Shift Left  | 5-420 |
| PSLLW/PSLLD/PSLLQ - Bit Shift Left  | 5-424 |
| PSRAW/PSRAD - Bit Shift Arithmetic Right                                    | 5-429 |
| PSRLDQ - Byte Shift Right   | 5-422 |
| PSRLW/PSRLD/PSRLQ - Shift Packed Data Right Logical                         | 5-433 |
| PSUBB/PSUBW/PSUBD/PSUBQ -Packed Integer Subtract                            | 5-443 |
| PSUBSB/PSUBSW -Subtract Packed Signed Integers with Signed Saturation       | 5-447 |
| PSUBUSB/PSUBUSW -Subtract Packed Unsigned Integers with Unsigned Saturation | 5-450 |
| PTEST- Packed Bit Test  | 5-438 |
| PUNPCKHBW/PUNPCKHWD/PUNPCKHDQ/PUNPCKHQDQ - Unpack High Data                 | 5-453 |
| PUNPCKLBW/PUNPCKLWD/PUNPCKLDQ/PUNPCKLQDQ - Unpack Low Data                  | 5-458 |
| PXOR - Exclusive Or   | 5-462 |

## Q

|                 |     |
|-----------------|-----|
| QNaNs encodings | 7-3 |
|-----------------|-----|

## R

|  |          |
|--|----------|
| RCPPS- Compute Approximate Reciprocals of Packed Single-Precision Floating-Point Values                    | 5-464    |
| RCPS - Compute Reciprocal of Scalar Single-Precision Floating-Point Value                                  | 5-467    |
| RDMSR instruction CPUID flag   | 2-50     |
| Real numbers notation  | 7-5, 7-6 |
| ROUNDPD- Round Packed Double-Precision Floating-Point Values   | 5-474    |
| ROUNDPS- Round Packed Single-Precision Floating-Point Values   | 5-478    |
| ROUNDSD - Round Scalar Double-Precision Value  | 5-481    |
| ROUNDSS - Round Scalar Single-Precision Value  | 5-483    |
| RSQRTPS - Compute Approximate Reciprocals of Square Roots of Packed Single-Precision Floating-point Values | 5-469    |
| RSQRTSS - Compute Reciprocal of Square Root of Scalar Single-Precision Floating-Point Value                | 5-472    |

## S

|  |                         |
|--|-------------------------|
| Self Snoop   | 2-52                    |
| SHUFPD - Shuffle Packed Double Precision Floating-Point Values               | 5-485                   |
| SHUFPS - Shuffle Packed Single Precision Floating-Point Values               | 5-488                   |
| SIMD floating-point exceptions, unmasking, effects of                        | 5-164, 7-13, 7-15, 7-18 |
| SNaNs  |                         |
| encodings  | 7-3                     |
| SpeedStep technology   | 2-47                    |
| SQRTPD- Square Root of Double-Precision Floating-Point Values                | 5-491                   |
| SQRTPS- Square Root of Single-Precision Floating-Point Values                | 5-493                   |
| SQRTSD - Compute Square Root of Scalar Double-Precision Floating-Point Value | 5-495                   |
| SQRTSS - Compute Square Root of Scalar Single-Precision Floating-Point Value | 5-497                   |
| SSE extensions   |                         |
| CPUID flag   | 2-52                    |
| SSE2 extensions  |                         |
| CPUID flag   | 2-52                    |
| SSE3   |                         |
| CPUID flag   | 2-46                    |
| SSE3 extensions  |                         |
| CPUID flag   | 2-46                    |
| SSSE3 extensions   |                         |
| CPUID flag   | 2-47                    |
| Stepping information   | 2-56                    |
| STMXCSR instruction  | 5-499                   |
| STMXCSR—Store MXCSR Register State   | 5-491                   |
| SUBPD- Subtract Packed Double Precision Floating-Point Values                | 5-499                   |
| SUBPS- Subtract Packed Single Precision Floating-Point Values                | 5-502                   |
| SUBSD- Subtract Scalar Double Precision Floating-Point Values                | 5-504                   |
| SUBSS- Subtract Scalar Single Precision Floating-Point Values                | 5-506                   |
| SYSENTER instruction   |                         |
| CPUID flag   | 2-50                    |
| SYSEXIT instruction  |                         |
| CPUID flag   | 2-50                    |

## T

|                    |      |
|--------------------|------|
| Thermal Monitor    |      |
| CPUID flag         | 2-52 |
| Thermal Monitor 2  | 2-47 |
| CPUID flag         | 2-47 |
| Time Stamp Counter | 2-50 |

## U

|  |       |
|--|-------|
| UCOMISD - Unordered Compare Scalar Double-Precision Floating-Point Values and Set EFLAGS | 5-508 |
| UCOMISS - Unordered Compare Scalar Single-Precision Floating-Point Values and Set EFLAGS | 5-510 |
| UNPCKHPD- Unpack and Interleave High Packed Double-Precision Floating-Point Values       | 5-512 |
| UNPCKHPS- Unpack and Interleave High Packed Single-Precision Floating-Point Values       | 5-514 |
| UNPCKLPD- Unpack and Interleave Low Packed Double-Precision Floating-Point Values        | 5-517 |
| UNPCKLPS- Unpack and Interleave Low Packed Single-Precision Floating-Point Values        | 5-519 |

## V

|  |       |
|--|-------|
| VBROADCAST- Load with Broadcast                    | 5-56  |
| Version information, processor                     | 2-31  |
| VEX  | 5-2   |
| VEXTRACTF128- Extract packed floating-point values | 5-140 |
| VEX.B  | 5-3   |
| VEX.L  | 5-3   |
| VEX.mmmmm  | 5-3   |
| VEX.pp   | 5-4   |

|  |           |
|--|-----------|
| VEX.R  | 5-5       |
| VEX.vvvv   | 5-3       |
| VEX.W  | 5-3       |
| VEX.X  | 5-3       |
| VFMAADD132PD/VFMADD213PD/VFMADD231PD - Fused Multiply-Add of Packed Double-Precision Floating-Point Values                               | 6-2, 7-26 |
| VFMAADD132SD/VFMADD213SD/VFMADD231SD - Fused Multiply-Add of Scalar Double-Precision Floating-Point Values                               | 6-10      |
| VFMAADD132SS/VFMADD213SS/VFMADD231SS - Fused Multiply-Add of Scalar Single-Precision Floating-Point Values                               | 6-13      |
| VFMAADDSUB132PD/VFMADDSUB213PD/VFMADDSUB231PD - Fused Multiply-Alternating Add/Subtract of Packed Double-Precision Floating-Point Values | 6-16      |
| VFMAADDSUB132PS/VFMADDSUB213PS/VFMADDSUB231PS - Fused Multiply-Alternating Add/Subtract of Packed Single-Precision Floating-Point Values | 6-20      |
| VFMSUB132PD/VFMSUB213PD/VFMSUB231PD - Fused Multiply-Subtract of Packed Double-Precision Floating-Point Values                           | 6-32      |
| VFMSUB132PS/VFMSUB213PS/VFMSUB231PS - Fused Multiply-Subtract of Packed Single-Precision Floating-Point Values                           | 6-36      |
| VFMSUB132SD/VFMSUB213SD/VFMSUB231SD - Fused Multiply-Subtract of Scalar Double-Precision Floating-Point Values                           | 6-40      |
| VFMSUB132SS/VFMSUB213SS/VFMSUB231SS - Fused Multiply-Subtract of Scalar Single-Precision Floating-Point Values                           | 6-43      |
| VFMSUBADD132PD/VFMSUBADD213PD/VFMSUBADD231PD - Fused Multiply-Alternating Subtract/Add of Packed Double-Precision Floating-Point Values  | 6-24      |
| VFMSUBPD - Fused Multiply-Subtract of Packed Double-Precision Floating-Point Values  | 6-43      |
| VFNMADD132PD/VFNMADD213PD/VFNMADD231PD - Fused Negative Multiply-Add of Packed Double-Precision Floating-Point Values                    | 6-46      |
| VFNMADD132PS/VFNMADD213PS/VFNMADD231PS - Fused Negative Multiply-Add of Packed Single-Precision Floating-Point Values                    | 6-50      |
| VFNMADD132SD/VFNMADD213SD/VFNMADD231SD - Fused Negative Multiply-Add of Scalar Double-Precision Floating-Point Values                    | 6-54      |
| VFNMSUB132PD/VFNMSUB213PD/VFNMSUB231PD - Fused Negative Multiply-Subtract of Packed Double-Precision Floating-Point Values               | 6-60      |
| VFNMSUB132SD/VFNMSUB213SD/VFNMSUB231SD - Fused Negative Multiply-Subtract of Scalar Double-Precision Floating-Point Values               | 6-68      |
| VINSERTF128- Insert packed floating-point values   | 5-156     |
| VMAKMOV- Conditional SIMD Packed Loads and Stores  | 5-169     |
| VPERM2F128- Permute Floating-Point Values  | 5-335     |
| VPERMILPD- Permute Double-Precision Floating-Point Values  | 5-327     |
| VPERMILPS- Permute Single-Precision Floating-Point Values  | 5-331     |
| VZEROALL- Zero All YMM registers   | 5-526     |
| VZERoupper- Zero Upper bits of YMM registers   | 5-528     |

## W

|                   |      |
|-------------------|------|
| WBINVD/INVD bit   | 2-34 |
| WRMSR instruction |      |
| CPUID flag        | 2-50 |

## X

|   |   |
|---|---|
| x87 FPU   |   |
| instruction opcodes   | B-23  |
| XFEATURE_ENABLED_MASK   | 5-530, 5-531  |
| XFEATURE_ENALBED_MASK   | 2-2   |
| XORPD- Bitwise Logical XOR of Packed Double Precision Floating-Point Values | 5-522   |
| XORPS- Bitwise Logical XOR of Packed Single Precision Floating-Point Values | 5-524   |
| XRSTOR  | 1-2, 2-2, 2-3, 2-4, 2-5, 2-11, 2-48, 2-57, 3-1, 5-13, 5-531                           |
| XSAVE   | 1-2, 2-2, 2-3, 2-4, 2-5, 2-11, 2-48, 2-57, 3-1, 5-13, 5-530, 5-531, 5-532, 5-533, 7-2 |

## Z

|                             |     |
|-----------------------------|-----|
| Zero, floating-point format | 7-3 |
|-----------------------------|-----|
